SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology***. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1994

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*

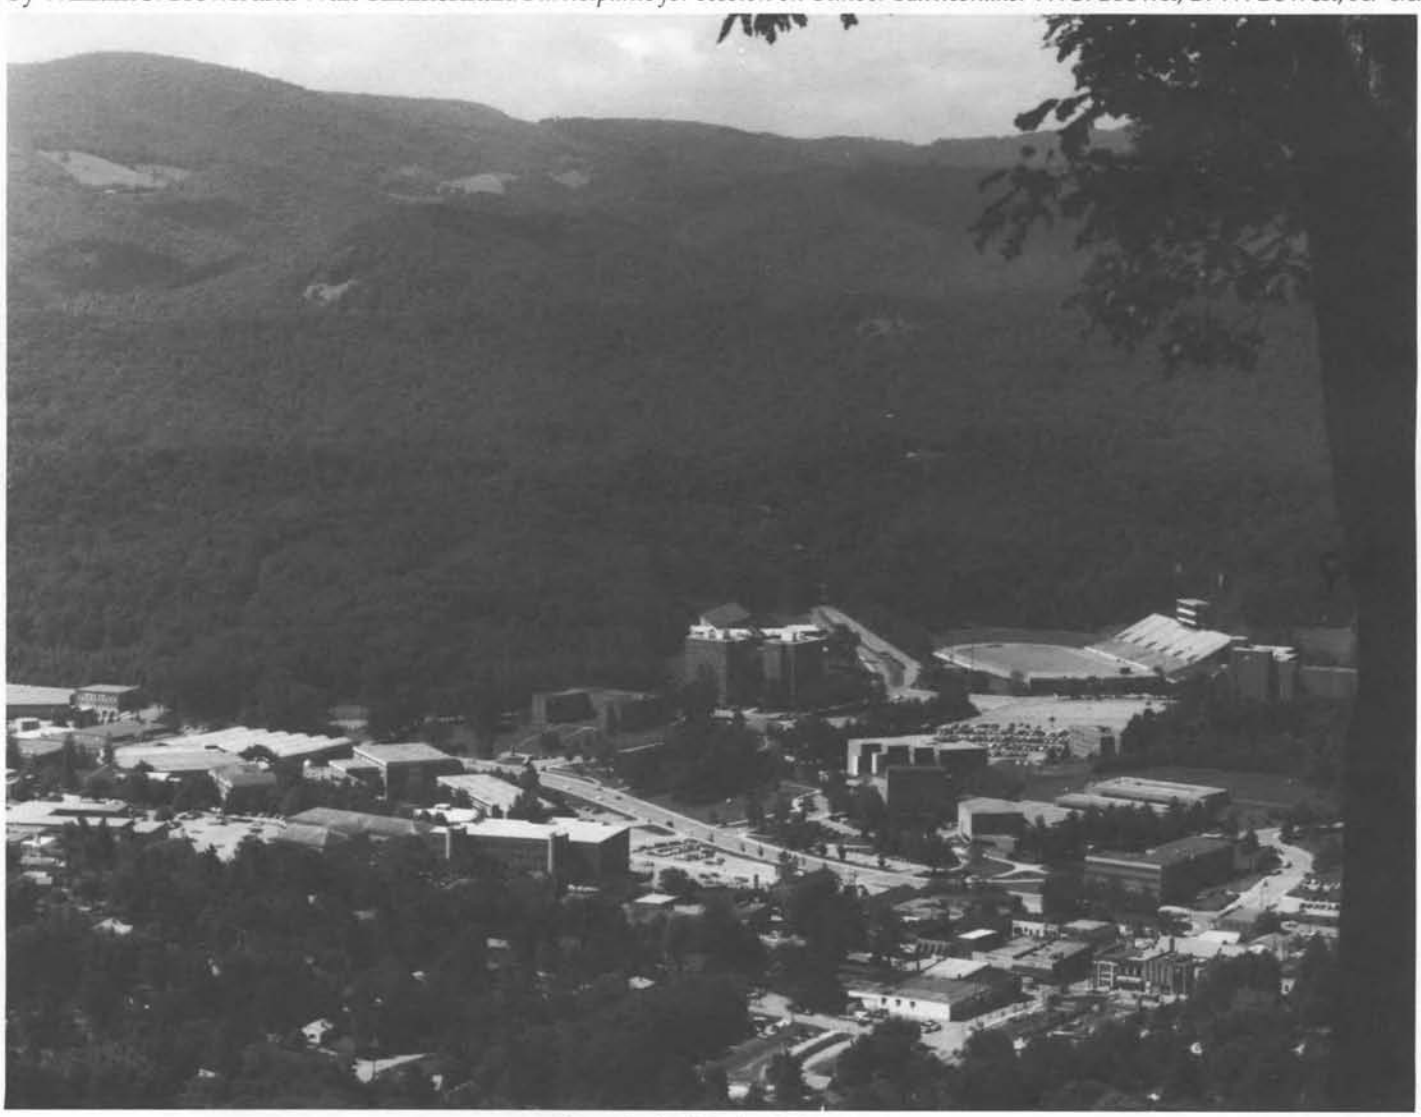
Institutional subscription.....$60.00

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

About the Cover.—The cover illustrations were executed by Jeffrey W. Tamplin, Department of Zoology & Physiology, Louisiana State University, Baton Rouge. Clockwise, from upper left: *Thamnophis exsul* (USNM 166423, holotype: Coahuila); *Thamnophis sumichrasti* (USNM 7079a: Veracruz); *Thamnophis scalaris* (MVZ 144489: Veracruz); *Thamnophis mendax* (LSUMZ 35340: Tamaulipas). Readers interested in the systematics of this group of Mexican garter snakes are referred to the following publication: D. A. Rossman. 1992. Taxonomic status and relationships of the Tamaulipan montane garter snake, *Thamnophis mendax* Walker, 1955. Proc. Louisiana Acad. Sci. 55:1–14.

1995 Annual Meeting
Society for the Study of Amphibians and Reptiles
38th Annual Meeting

8–13 August 1995



Appalachian State University, Boone, North Carolina

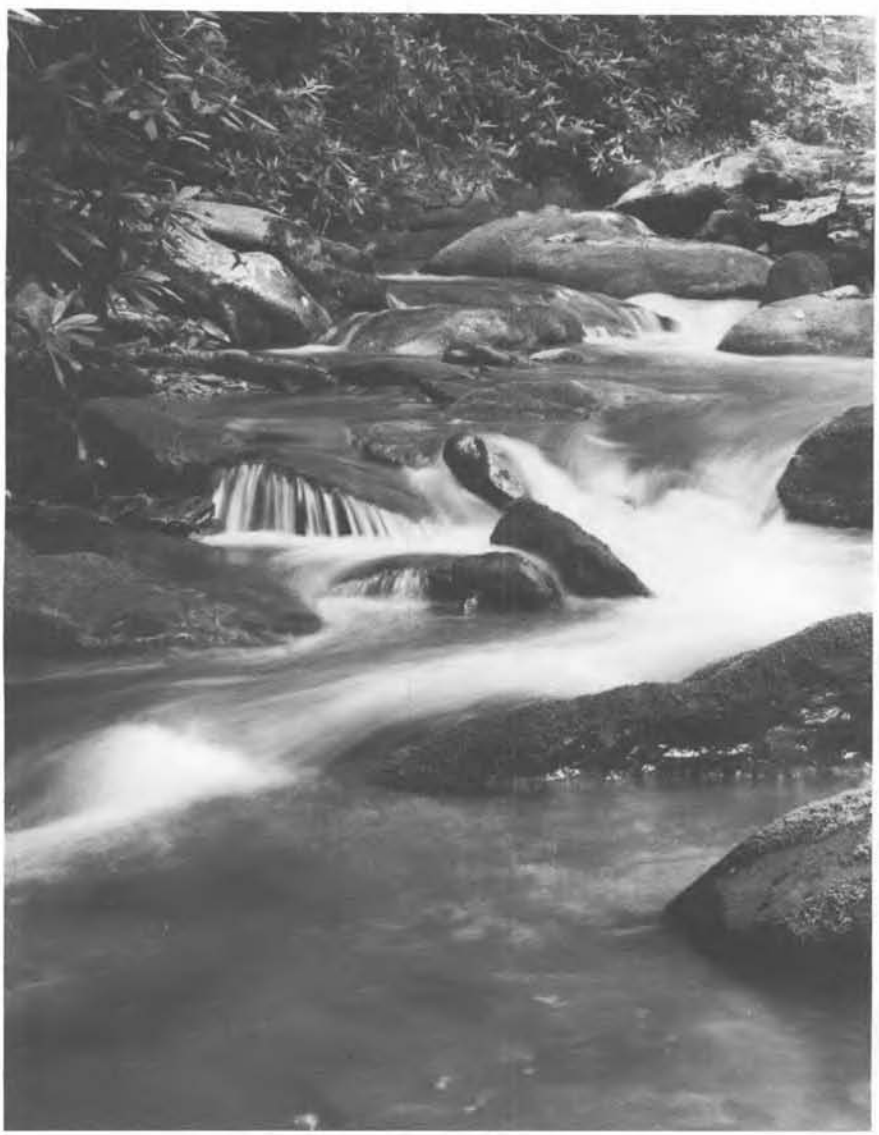
The members of the Biology Department and Office of Conferences and Institutes at Appalachian State University take great pleasure in inviting y'all to come and visit us next August. We have one of the nicest settings you can imagine and all the modern facilities necessary to ensure that your meeting in Boone will be a resounding success. Escape the heat and humidity (or at least one of these) and come up the mountain.

Meeting Announcement: The formal announcement brochure will be mailed to North American members of SSAR by the middle of January 1995. Overseas members and non-members can receive the brochure by contacting Wayne Van Devender (see page 135 for address and contact numbers). This booklet will include final descriptions of all activities, call for papers, pre-registration forms, and full information on accommodations.

Keynote Address: The Keynote Address will be given by Dr. Judy Stamps of the University of California, Davis ("TERRITORIAL BEHAVIOR: TESTING THE ASSUMPTIONS").

Symposium: "EASTERN RATTLESNAKES: BIOLOGY AND CONSERVATION OF *CROTALUS HORRIDUS* AND *CROTALUS ADAMANTEUS*" organized by William S. Brown and Walt Timmerman. *Participants for session on Timber Rattlesnake:* W. S. Brown, B. W. Bowen, A. -M.

Clark, L. M. Bushar, H. K. Reinert, D. E. Keyler, B. L. Oldfield, R. Stechert, A. Breisch, S. H. Harwig, S. Smith, W. H. Martin, E. Possardt, T. Tyning, R. T. Zappalorti, D. Wynn, A. H. Savitzky, B. A. Savitzky, G. Rocco, J. B. Sealy, A. Soha, J. T. Taylor, A. C. Smith, Jr., K. Michell, R. R. Rupert, Jr., D. F. Fraser, J. Congdon. *Participants for session on Eastern Diamondback Rattlesnake:* W. Timmerman, W. Auffenberg, W. H. Martin, D. B. Means, G. Dalrymple, P. Kain, S. Telford, J. W. Gibbons, R. Mount, L. Jones.



Special Regional Societies Conference: "Regional Herpetological Societies: Programs and Projects," organized by Martin J. Rosenberg.

Workshop: "Herp Photography" by David Dennis and Eric Juterbock.

Contributed Papers & Poster Presentations: There will be several concurrent sessions each day. All sessions will be held at the Broyhill Inn at Appalachian State University. Previous experience indicates that these rooms will cover our needs for spaces, both large and small. Rooms are close together, so people (but not a lot of noise) can move freely from room to room. Presentations of either type must include an informative abstract and will be accepted on a first come, first served basis.

Student Paper Award: Seibert Prizes will be awarded to the two best student papers ($250 first prize, $150 second prize).

Student Travel Grants: Ten awards of $200 each will be given. For details see SSAR Business in this issue (page 136).

Winkler's Creek near the ASU campus.

Multimedia Presentations: "Herps of the West" and "Amphibians of the Appalachians," by David Dennis and Eric Juterbock; "Herpetological Namesakes," by Kraig Adler and David Dennis.

Social Programs: Welcome social, Wednesday night, 9 August. Barbecue dinner, Thursday, 10 August ($20 per person). Graduate student social, Friday, 11 August. Multimedia presentations, Friday, 11 August. Annual SSAR auction, Saturday, 12 August. SSAR President's Travelogue Slide Shows, time to be announced.

Field Trips: Trips to Grandfather Mountain, Linville Gorge Wilderness Area, and more are planned, as well as night trips for salamander watching. Several spouse tours are also anticipated. See the upcoming announcement brochure for the latest arrangements and options.

Exhibits: Numerous merchants and artists will be on hand. Usual exhibits include books, reprints, artwork, t-shirts, field equipment, regional herp societies, photography, etc. A photographic display of all members of the *Plethodon glutinosus* complex is under consideration. Poster sessions and audiovisual shows are also open to the public.

Live Exhibits: Herps of the region, sponsored by the North Carolina Herpetological Society and Appalachian State University. As usual, a diverse array of animals will be available for viewing and photography.

Accommodations: Boone, North Carolina is a popular summer resort area. Reservations should be made well in advance. Lodging at Broyhill Inn (meeting site) will be $40 (single occupancy) or $46 (double occupancy) per day. Dormitory rooms for 200 people are available for approximately $15 (single occupancy) or $10 (double occupancy) per day plus $8 for linen. Approximately 100 additional rooms are reserved at several local motels for $49–$70 per day.

Travel and Parking: The recommended airport in the region is in Charlotte, North Carolina, which is about 110 miles and two hours driving time from Boone. If you have interests in visiting other parts of North Carolina or simply wish to have some mobility, it will be best to arrange a rental car at the airport. Most larger firms have offices in Charlotte. To accommodate other travelers Appalachian State University will provide limited shuttle service to Charlotte for a nominal fee of $20 each way. Scheduling will be restricted due to limited motor pool resources, and some passengers may have substantial waits at the airport. Parking will not be regulated on the Appalachian State University campus during this period, and abundant, free parking will be available. Shuttle transportation will be available from dormitories and motels to the Broyhill Inn.

Family Programs: A number of family activities will be offered, including tours of Boone and surrounding areas, regional craft fairs, etc.

Collecting Permits: Scientific collecting permits are required for taking and holding more than five reptiles and ten amphibians. Requests and/or questions should be sent to *Randall C. Wilson, Nongame Section Manager, Division of Wildlife Management, North Carolina Wildlife Resources Commission, 512 N. Salisbury Street, Raleigh, North Carolina, 27604-1188, USA (tel. 919-733-3391).*

Meals: University cafeterias will not be functioning during our meeting. Boone has the usual group of fast food restaurants and a number of places with more atmosphere. The Broyhill Inn (meeting site) has an excellent restaurant.

Registration: A booth at Broyhill Inn will be staffed at convenient hours to handle your registration and answer questions.

Pre-registration: All persons attending the meeting must pay the registration fees. These fees pay for printing, mailing, administration, social events, coffee breaks, etc. We can accept payments only in U.S. dollars and checks drawn on U.S. banks. Registration fees, if received *before 15 April 1995*, are: $75 for students, $110 for regular members, and $50 for spouses. After 15 May, registration fees will be $115, $145, and $50, respectively.

Climate: The campus of Appalachian State University lies at just above 3300 ft (1005 m) in elevation. In August you can expect cool nights (down to about 50°F) and at least a few rainy days during the meetings. Daytime temperatures rarely exceed 85°F. Most buildings are not, and do not need to be, air-conditioned.

Questions: Further details, call for papers, pre-registration and abstract forms will be mailed to all US, Mexican, and Canadian members of SSAR by January 1995. Overseas members may request these materials by mail. Address any questions about the program or field trips, or request materials from ***Dr. Robert Wayne Van Devender, Department of Biology, Appalachian State University, Boone, North Carolina 28608, USA (tel. 704-262-2665, fax 704-262-2127, e-mail vandevenderr@appstate.edu).*** Address questions about meeting sites, rooms, registration, etc., to ***Richard Hudson, Office of Conferences and Institutes, University Hall (tel. 704-262-3045; fax 704-262-4992; e-mail hudsonre@appstate.edu).***

Several field trips are planned in conjunction with the meeting, including one to nearby Grandfather Mountain, home of *Plethodon yonahlossee* (shown here), *P. welleri*, *P. jordani*, and *Desmognathus wrighti*. Grandfather Mountain and Yonahlossee Road at its base are forever enshrined in herpetological lore through Emmett R. Dunn's field work there in the 1920s and the eloquent preface to his book on the family Plethodontidae (1926). In 1931, a Cincinnati teenager, Worth Hamilton Weller, lost his life in a fall off Grandfather Mountain, after a successful search for the new species of salamander that was later named for him.

SSAR BUSINESS

SSAR 1994 Annual Meeting in Athens

Nearly 500 herpetologists converged on Athens, Georgia between 28 July and 1 August 1994 as SSAR held its 37th annual meeting, concurrently with the annual meeting of the Herpetologists' League. Almost all of the meeting events took place at the Georgia Center, on the campus of the host institution, the University of Georgia; Josh Laerm and Whit Gibbons were the Local Committee co-chairs.

The traditional, though unofficial, beginning of the meeting was the annual meeting of the SSAR Board of Directors, who met on Wednesday, 27 July 1994, between 1000 and 1740 hours (excluding a total of 90 minutes for a luxurious lunch in the Georgia Center dining room). At the time we were called to order, attendees included all officers: Bob Aldridge, Tom Fritts, Lynne Houck, Eric Juterbock, Al Savitzky, and Karen Toepfer; directors Robin Andrews, Paul Moler, and Bern Tryon; editors representing all of the SSAR publications: Kraig Adler, Joe Collins, Steve Corn, Bob Hansen, Bob Powell, Rich Seigel, and Tom Tyning; several coordinators or committee chairs: Randy Krohmer, George Pisani, and Eric Rundquist; immediate past treasurer Doug Taylor; and, several members including Bill Brown, Jim Christiansen, Jim Murphy, John Wright, and Wayne Van Devender. Others appeared during the day to make reports or observe the goings on. A summary of business conducted was presented at the Business Meeting (see below).

Presentations

Even before the official opening of the meeting, we had academic business to attend to. Wednesday evening, from 2000 to 2200 hours saw a packed house for a Point-Counterpoint Forum: Issues in Conservation, moderated by Bob Jaeger. Henry Wilbur and Brad Shaffer discussed the reality and significance of the apparent amphibian decline. The meeting was officially called to order at 0830 on Thursday, 28 July 1994 to begin the plenary session. After the welcomes and opening announcements, we were treated to the Keynote Address/Distinguished Herpetologist Lecture, "The Evolution of Reptilian Viviparity Revisited" by Richard Shine.

Scholarly presentations were made in 27 contributed paper sessions, two poster sessions (of two days each), three symposia and one colloquium between 1330 hours on the 28th and 1600 hours on the 1st. Over 250 authors contributed approximately 150 papers and over 100 authors presented nearly 50 posters. The three symposia (Field and Behavioral Endocrinology, Reptile and Amphibian Life History Interfaces, West Indian Herpetology) involved 65 authors and 50 papers; The Turtle Phylogeography Colloquium, 12 authors of 12 papers.

Social Program

To judge from the density of scholarly activity during the five days, one might not expect much time to be sociable. Our UGA/SREL hosts, however, managed to squeeze in a plethora of events designed to entertain and enlighten us, as well as occasionally entice us into spending money. A huge exhibit of literature, art, tee-shirts, and herpetological equipment was located in the center of all Georgia Center activities, and a massive exhibit of live amphibians and reptiles (organized by Wayne Van Devender and the SREL crew) was located just upstairs; both for the duration of the meeting. A herptile art exhibit was located in the nearby Ecology Building for most of the meeting as well.

Social events were frequent, and offered more fine edibles and liquid refreshments than we were able to consume (though not for lack of trying!). There was an Ice Breaker Social on Thursday evening, a Graduate Student Social on Friday evening, a barbecue at the State Botanical Garden on Saturday night, and, of course, the traditional SSAR Auction, with Joe Collins as Auctioneer, was held on Sunday night, the 31st. It was at this event that Auctioneer Collins announced the winning bids for the SSAR Student Travel Awards Silent Auction. This silent auction had been going on for several days. It was organized by students Dawn Wilson and John Krenz to collect money to be used to fund travel grants to students attending the annual meeting.

The annual multimedia extravaganza was held on Friday evening, and the long string of trouble-free airings ended as a handful of minor equipment problems caused the program to get off to a slow start. Still, a huge crowd enjoyed the presentations of "Herpetology of the West" and "Amphibians of the Appalachians" by Dave Dennis and Eric Juterbock. They were treated to the premiere of a new program by Kraig Adler and Dave Dennis: "Herpetological Namesakes." This latter program, which used examples from around the world and all major groups of herptiles, first presented a photo of an animal, then a photo of its namesake, and finally a caption which told the story. It was especially appreciated by the audience. A SRO crowd was on hand Monday to be overwhelmed by the Third Annual President's Travelogue, held in the Ecology Building auditorium. Ric Shine (Australian snakes), Jan Caldwell (Brazilian frogs), and Rob Stuebing (herps of Sarawak) combined beautiful images of their favorite animals with insightful commentary.

Business Meeting

President Lynne Houck called to order the Annual Business Meeting at 1530 hours on Monday, 1 August 1994, in the Mahler Auditorium of the Georgia Center. After welcoming those present and making a few introductory remarks, President Houck announced the winners of the Kennedy and Seibert Awards (see announcements later in this issue). Twelve students competed for the Kennedy Award this year and 26 for the Seibert Award.

Secretary Juterbock reported on the business conducted at the Board Meeting on Wednesday. Said meeting was neither exceptionally long nor particularly contentious; virtually all business other than the budget involved receiving reports of the editors and committee chairs. Our publications are all in fine shape and growing; the number of submissions to *Journal of Herpetology* and *Herpetological Review* continues to increase. The latter plans to add color covers in the near future. The *Catalogue* still could use accounts by senior researchers and on North American taxa. Kraig Adler announced that four *Facsimiles* are due in 1995: Fitzinger's "Neue Classification der Reptilien" (1826), Gray and Gunther's "Lizards of Australia and New Zealand" (1845–1875), Stejneger's "Herpetology of Japan and Adjacent Territory" (1907), and Wilhelm Peters's "Herpetological Contributions." Two *Contributions* are due in 1995: Anderson's "Lizards of Iran" and Powell and Henderson's "West Indian Herpetology: a Symposium in Honor of Albert Schwartz." *Herpetological Circulars* will publish Beltz's "Original Citations for North American (North of Mexico) Amphibians and Reptiles." Steve Corn announced that our new series, *Herpetological Conservation*, has an editorial board and has solicited manuscripts; he hopes to have the first volume printed during 1995.

Ken Dodd reported for the Conservation Committee and read a number of resolutions (see below), which were all adopted. The Grants-in-Herpetology Committee announced that it wishes to increase the size of awards, and encouraged members to contribute to the GIH endowment. The slate of nominees for the 1994 election was read; there were no additional nominations from the floor, and the slate was accepted by acclamation.

Immediate past treasurer Doug Taylor reported that SSAR was in excellent financial shape due to the budgetary officers staying within budget and tremendous sales of publications. Treasurer Karen Toepfer reported that the 1994 picture was just as good. She announced that we were both increasing the number of our programs and adding to current programs and publications; thus we were increasing all dues categories except for students.

Wayne Van Devender, Local Committee Chair for the 1995 meeting in Boone, North Carolina, invited us all to join him in salamander heaven (see announcement elsewhere in this issue). Field trips, a Grandfather Mountain event, a Rattlesnake symposium and a Keynote Address by Judy Stamps, "Lizard Territoriality: Testing the Assumptions" are only a few of the highlights of this meeting. He encouraged everyone to pre-register early.

George Pisani read the remaining resolutions, which were all accepted by the membership, and no new business was introduced. So, after President Houck transferred the SSAR Presidential Gavel to President-elect Al Savitzky, he adjourned the meeting at 1635 hours.

1994 Joint Resolutions

Society for the Study of Amphibians and Reptiles and The Herpetologists' League

Protection of Indian Sea Turtles (Joint)

WHEREAS India has historically supported the largest worldwide nesting site of the olive ridley sea turtle (*Lepidochelys olivacea*) at Gahirmatha Beach (Bhitarkanika Sanctuary) in Orissa; and,

WHEREAS Gahirmatha Beach represents one of only four remaining mass-nesting beaches for this species in the entire world and is the only such site in the Indian and Western Pacific Oceans; and,

WHEREAS actions of the Orissa State Government to develop a major shrimp fishery at the Port of Talchua threaten migratory breeding populations of this species at Gahirmatha Beach; and,

WHEREAS the incidental capture of sea turtles by shrimp fishing fleets has been demonstrated to be especially destructive to sea turtle populations, and various other human activities, especially egg poaching, have for many years adversely affected sea turtles; and,

WHEREAS for the forseeable future the Madras hatcheries for the olive ridley serve to mitigate some of the damage caused to populations by egg poachers; and,

WHEREAS the sea turtles of the world are an international resource that in the course of their lives travel in and out of sovereign waters of many nations and into international waters; and,

WHEREAS these nations, most recently México, have developed and are vigorously enforcing conservation programs for this and other sea turtle species to maintain this sustainable economic resource in accordance with guidelines of the Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES);

NOW IN VIDEO!

AUFFENBERG ON MONITORS

SSAR is pleased to announce its first video production, a recording of the lecture by Professor Walter Auffenberg (University of Florida) presented at the society's 1993 Annual Meeting in Bloomington, Indiana. In this 60-minute video, which is extensively illustrated with color slides, graphs, and other figures, Auffenberg describes and contrasts the behavioral ecology and feeding strategies of three markedly different species of monitors—the Komodo Monitor of eastern Indonesia, Gray's Monitor of the Philippines, and the Bengal Monitor of South Asia. Each species has been the subject of a major book by Auffenberg, and that on the Bengal Monitor was just published by the University Press of Florida. The video includes several film sequences of Komodo Monitors in the wild.

Videotapes may be purchased from DUANE BUSICK VIDEO PRODUCTIONS, 4400 ETTER ROAD, BLOOMINGTON, INDIANA 47408, USA, for US$20 each in the USA, $25 outside the USA (prices include all shipping and handling as well as airmail postage overseas). Payment may be made by personal checks or money orders, *in advance*; sorry, no credit cards or CODs. This is a VHS format tape (NTSC standard, appropriate for USA VCR machines); those who need PAL or SECAM versions may convert from NTSC copies or inquire of Busick Video for additional charges for PAL or SECAM versions (telephone area 812, 336-8329).

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles (SSAR) and The Herpetologists' League (HL), international professional scientific societies devoted to the study of amphibians and reptiles, strongly encourage the Government of

India to give serious consideration to relocating the proposed Talchua shrimp fishery to existing facilities at Paradeep and/or Dhamara; and, be it further

RESOLVED that these societies strongly encourage India's government to require and enforce the use of Turtle Excluder Devices by all shrimp trawlers; and, be it further

RESOLVED that these societies strongly encourage India's government to work with the Government of Orissa to preserve the Gahirmatha Beach nesting site and develop eco-tourism to it to bolster the Orissan economy; and, be it further

RESOLVED that these societies strongly encourage India's government to continue the sea turtle hatchery management programs at Madras; and, be it finally

RESOLVED that these societies strongly encourage India's government to develop and enforce vigorously laws to halt egg poaching at sea turtle nesting sites.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles and The Herpetologists' League, 25 April 1994.

The California Desert Protection Act
(H.R. 518, S. 21 and variants thereof)

WHEREAS the Congress of the United States is considering the passage of legislation to designate up to 8 million acres of public land as parks and wilderness in the southern deserts of California, and

WHEREAS the designation would add 1.1 million acres to Death Valley National Monument and upgrade it to a national park, and

WHEREAS over 1 million acres would add 300,000 acres to Joshua Tree National Monument and upgrade it to a national park, and

WHEREAS over 1 million acres will be designated as the East Mojave National Park or the Mojave National Preserve, and

WHEREAS the designation of such lands would provide additional and important protection for desert plants and wildlife, including desert tortoises, bighorn sheep, and other species of significance, and

WHEREAS the designation of such lands provides a complementary level of protection to other lands identified as critical habitat for the recovery of the federally threatened Mojave metapopulation of the desert tortoise, and

WHEREAS the designation of such lands would preserve fragile desert ecosystems for the benefit of future generations of Americans, and

WHEREAS the lands encompassed are of high biological and cultural significance,

THEREFORE, be it
RESOLVED that The Herpetologists' League and the Society for the Study of Amphibians and Reptiles at their joint annual meeting at the University of Georgia, 29 July to 1 August 1994, endorse the swift passage of an inclusive and effective version of the California Desert Protection Act.

Establishment of Incidental Take Levels for Sea Turtles

WHEREAS many thousands of endangered and threatened sea turtles have washed ashore along the Gulf and Atlantic coasts of the United States as a result of incidental take by certain commercial fisheries, and

WHEREAS an unacceptable number of sea turtles continue to be killed by commercial fishing activities throughout waters of U.S. jurisdiction, and

WHEREAS the same temporal pattern of mortality has continued for decades thereby decimating the large-juvenile and adult populations, and

WHEREAS the responses of the Department of Commerce, the responsible agency for protecting these animals on the endangered species list, have been based mainly on the modification of a single fishing technology (turtle excluder devices or TEDs in shrimp nets); and the Department of Commerce has apparently considered the remaining mortality acceptable incidental "take" under the Endangered Species Act, and

WHEREAS unless new actions are taken, the chances for improvement in the status of threatened and endangered populations will continue to decline,

THEREFORE, be it
RESOLVED that the Herpetologists' League and the Society for the Study of Amphibians and Reptiles at their joint annual meeting at the University of Georgia, 29 July to 1 August 1994, hereby request that the Secretary of Commerce:

(1) contract for an advisory group of the National Academy of Sciences (with such individuals as used for the study required by Section 1008 of the Endangered Species Act Amendments of 1988) to establish the maximum allowable incidental "take" within a reasonable time limit (one to two week period) in a fishery zone by commercial fisheries and the consequences of exceeding that quota, and

(2) that the Secretary of Commerce follow the guidelines properly to carry out his/her responsibilities under the Endangered Species Act to protect these species by all means necessary, including (a) temporary closing of fishery zones, (b) restrictions on dumping bi-catch which attracts sea turtles, (c) initiation of new studies of sea turtle physiology and pathology, (d) modifications of handling procedures following incidental catch, (e) and the establishment of non-fishing zones as control areas for ecological and behavioral studies that would afford some protection to remaining stocks of sea turtles.

Reauthorization of the Endangered Species Act

WHEREAS the diversity of native species of animals and plants is being reduced by human activities, and

WHEREAS the reduction in biological diversity is a consequence of habitat loss and degradation and from the introduction of non-native species, and

WHEREAS biological diversity and natural ecosystems are important components of our natural heritage, and

WHEREAS the purpose of the Endangered Species Act is to prevent the loss of biological diversity and the natural ecosystems on which plants and animals depend, and

WHEREAS the Endangered Species Act is up for reauthorization and funding by the U.S. Congress,

THEREFORE, be it
RESOLVED that The Herpetologists' League and the Society for the Study of Amphibians and Reptiles at their joint annual meeting at the University of Georgia, 29 July to 1 August 1994, urge the Congress of the United States to support passage of a strong version of the Endangered Species Act such as that presently embodied in H.R. 2043 and S. 921.

Increased Federal Funding for National Wildlife Refuges in Florida

WHEREAS the protection of natural habitat is essential to the conservation of native species, and

WHEREAS the U.S. Fish and Wildlife Service has identified two regions of Florida, the Lake Wales Ridge of central Florida and the Atlantic coast beaches of east-central Florida, as providing essential habitat for a broad diversity of threatened and endangered species, and

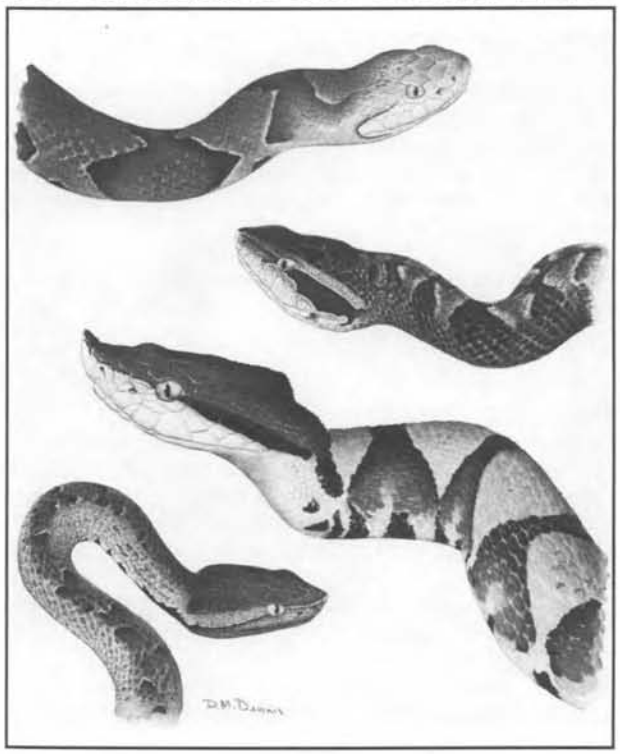
WHEREAS the first of these, designated as the Lake Wales Ridge National Wildlife Refuge, is critical to the survival of numerous plants and animals, including at least three species of reptiles that exist nowhere outside of Florida, and

WHEREAS the second of these, designated as the Archie Carr National Wildlife Refuge, serves as a nesting beach for three species of sea turtles, including the densest aggregation of nesting loggerhead turtles in the Western Hemisphere, and

WHEREAS both of these sites occur in regions that are subject to some of the greatest rates of human-mediated habitat destruction anywhere in the United States,

THEREFORE, be it
RESOLVED that the Herpetologists' League and the Society for the Study of Amphibians and Reptiles at their joint annual meeting at the University of Georgia on 29 July to 1 August 1994, commend the U.S. Congress for allocating initial funding for the acquisition of land in both refuges.

However, in recognition that the funds thus far allocated represent only a small fraction of the needed resources, we therefore urge substantially increased federal funding for the acquisition, in conjunction with designated state and local funds, of biologically critical and highly endangered lands within both refuges, and, be it further



RESOLVED that copies of this resolution shall be provided to the Secretary of the Interior, Director of the U.S. Fish and Wildlife Service, Chairs of the House and Senate Appropriations Committees, Senators Bob Graham and Connie Mack of Florida, and other appropriate persons.

PCR and Scientific Research on Endangered Species

WHEREAS biological information on endangered species is a necessary prerequisite to any effective conservation program, and

WHEREAS United States biologists are required by law to obtain research permits from the U.S. Fish and Wildlife Service Office of Management Authority (OMA) to conduct conservation-related research on endangered species, and

"SNAKES OF THE *AGKISTRODON* COMPLEX"

SIGNED LIMITED-EDITION COLOR PRINT

SSAR is pleased to offer signed-and-numbered copies of the frontispiece to its book, "Snakes of the *Agkistrodon* Complex" by H. K. Gloyd and Roger Conant (published 1990). This full-color print is reproduced from a watercolor by the well-known wildlife artist, David M. Dennis. Each copy is individually signed by Dr. Conant and Mr. Dennis and is numbered in an edition strictly limited to 117 copies. Each print measures 8.75 x 11.5 inches (22 x 29.5 cm) and is printed on acid-free paper suitable for framing.

ORDERING: Send orders to Dr. Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103, USA (*telephone*: area code 314, 658-3900 or 658-3916; *fax*: 314, 658-3117).

PRICE: $25, including shipping.

WHEREAS recent experience has shown that permits for standard scientific procedures can take months or years to obtain from OMA, and such delays often constitute a substantial obstacle to conservation-oriented research, and

WHEREAS OMA often imposes extensive conditions on endangered species permits, and such conditions can constitute a substantial obstacle to conservation-oriented research, and

WHEREAS OMA often imposes extensive conditions on collaborative research conducted by foreign nationals on their native soil, and

WHEREAS OMA recently has claimed jurisdiction over synthetic DNA generated by polymerase chain reaction (PCR) methodology, despite the fact that synthetic DNA can be obtained nondestructively and contains no part of the original (endangered species) DNA, and

WHEREAS at the last two meetings of the Convention on International Trade in Endangered Species (CITES), a proposal was forwarded to exempt small tissue samples from CITES regulations, in recognition of the importance of conservation-oriented research, and that both times this proposal was opposed by the U.S. representative (OMA), and

WHEREAS as the biodiversity crisis gains momentum, there is no time to waste on non-essential restrictions on conservation-oriented research.

THEREFORE, be it
RESOLVED that 1) The Herpetologists' League (HL) and the Society for the Study of Amphibians and Reptiles (SSAR) at their joint annual meeting at the University of Georgia, 29 July to 1 August 1994, call upon the Secretary of the Interior, the Director of the U.S. Fish and Wildlife Service, and the Chief of the Office of Management Authority to work with scientists under the spirit of the Endangered Species Act, rather than adopt an interpretation of regulatory control which works to the detriment of conservation goals.

2) The HL and SSAR call upon the U.S. Office of Management Authority to recognize the importance of biological research in conservation, and to facilitate conservation-oriented research by making permits available to biologists in a timely and efficient manner.

3) The HL and SSAR call upon the U.S. Office of Management Authority to issue permits without extensive and unnecessary conditions, and without attempting to modify or second-guess the scientific methodology.

4) The HL and SSAR call upon the U.S. Office of Management Authority to allow free exchange of synthetic DNA for biological research, in recognition of the fact that synthetic DNA has no commercial value but has extensive scientific and conservation value.

5) The HL and SSAR call upon the U.S. Office of Management Authority to support the proposal to exempt small tissue samples (< 1 gram), small blood samples (< 1 ml) and DNA isolates from CITES regulations, in recognition of the fact that these scientific specimens have no commercial value but have extensive scientific and conservation value.

6) The HL and SSAR call upon the U.S. Office of Management Authority to exercise extreme restraint in imposing conditions on endangered species research outside the United States, in recognition of the fact that such actions diminish the spirit of cooperation necessary for international conservation, and in recognition of the fact that domestic permit agencies are the appropriate regulatory body for research conducted within the territorial boundaries of sovereign nations.

Listing Box Turtles on Appendix II of CITES

WHEREAS box turtles (genus *Terrapene*) are important ecological and aesthetic components of the terrestrial ecosystems of North America where they historically reached high population densities, and

WHEREAS box turtles are long-lived species whose adults maintain high survivorship despite substantial mortality of juveniles and young, and

WHEREAS the large-scale removal of breeding adults of such long-lived species exacerbates already existing problems such as loss of habitat, highway mortality, and habitat fragmentation, and

WHEREAS box turtle populations in many parts of North America are declining despite local or state protection, and

WHEREAS the international export of box turtles to Europe and Japan has exploded within recent years to the extent that more than 70,000 individuals were exported during the last three years alone, and

WHEREAS the uncontrolled exploitation of such long-lived species will eventually lead to the extirpation of many populations for a purpose which is unconscionable under present concerns for ecosystem biodiversity, and

WHEREAS box turtles (genus *Terrapene*) have been proposed by the U.S. Fish and Wildlife Service to be added to Appendix II of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) at the forthcoming meeting in Fort Lauderdale in November,

THEREFORE, be it
RESOLVED that the Herpetologists' League (HL) and the Society for the Study of Amphibians and Reptiles (SSAR), at their joint annual meeting at the University of Georgia 29 July to 1 August 1994, support the listing of the genus under provisions of Appendix II; and, be it further

RESOLVED that HL and SSAR urge the U.S. Fish and Wildlife Service to vigorously pursue data relating to the international trade of all native chelonians to ensure that other species are not likewise jeopardized by unregulated trade; and, be it further

RESOLVED that HL and SSAR urge the U.S. Fish and Wildlife Service and other federal and state resource agencies to support research designed to assess and monitor chelonian populations on a long-term basis.

Honoring Jack McCoy

WHEREAS Jack McCoy was an exceptionally valued friend and mentor to many in the herpetological community; and,

WHEREAS Jack McCoy devoted much time and effort to advancing the goals and stature of both the Herpetologists' League and the Society for the Study of Amphibians and Reptiles; and,

WHEREAS Jack McCoy's untimely sudden death on 7 July 1993 has left a palpable void both in the field of herpetology and in the lives of friends and associates;

THEREFORE, be it
RESOLVED that these societies hereby express their most heartfelt sense of loss of a friend and colleague.

Adopted unanimously by The Herpetologists' League and the Society for the Study of Amphibians and Reptiles at their joint annual meeting at the University of Georgia, 29 July to 1 August 1994.

Thanking The Local Committee

WHEREAS The University of Georgia at Athens has provided an excellent setting, fine food and accommodations for this joint meeting of the Society for the Study of Amphibians and Reptiles and The Herpetologists' League; and,

WHEREAS the Savannah River Ecology Laboratory has a long and distinguished tradition of research in ecology and herpetology; and,

WHEREAS the choices of seminar rooms has done much to further a feeling of closeness between members of these societies; and,

WHEREAS Joshua Laerm is to be commended for his observance of these societies' tradition of consumption of cereal-malt beverages.

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles and The Herpetologists' League extend their most sincere thanks to the Local Committee: Whit Gibbons, Norma Reed, Joshua Laerm, Janice Sands, Amy Edwards, Bobby Bowen, Elizabeth McGhee, Joe Morgan, Martina Conrad, David Brooks, Christine LaPorte, Kurt Buhlmann, Tony Mills, Dawn Wilson, Wayne Van Devender, John Krenz, and also to Vinny Burke, Mark Mills, John Lee, Michael Schwartz, and the other SREL and UGA students whose combined efforts have made this meeting a successful intellectual and social event; and, be it further

RESOLVED that these societies offer sincere apologies to Joshua Laerm for the obviously diminished imbibational capacity of the membership at the Social.

Adopted unanimously by The Herpetologists' League and the Society for the Study of Amphibians and Reptiles at their joint annual meeting at the University of Georgia, 29 July to 1 August 1994.

1994 SSAR Resolution

Honoring Outgoing SSAR Officers and Editors

WHEREAS the following individuals have given freely of their time, skills, insight, and knowledge to the Society for the Study of Amphibians and Reptiles in this past year; and,

WHEREAS they have been therefore instrumental in advancing the Society's goals and furthering its growth as an international scientific society; and,

WHEREAS SSAR is dependent upon the generosity of these persons and those who have gone before them, and is greatly indebted to them for their fine efforts in its behalf;

THEREFORE, be it
RESOLVED that the Society for the Study of Amphibians and Reptiles urges these persons not to ride off into the sunset, but rather to continue to be available, with or without official titles, as resources to guide those who follow; and, be it further

RESOLVED that the Society offers its most sincere thanks to the following persons who have served in these capacities:

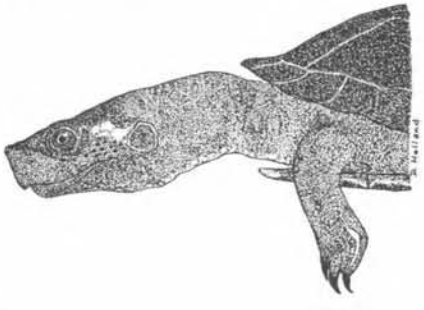
WILLIAM E. COOPER— Chair, Nominating Committee
CHARLES COSTA— Elector
THOMAS H. FRITTS— President
RONALD GOELLNER— Chair, Zoo Liaison Committee
LOUIS J. GUILLETTE— Director
STEPHEN H. HAMMACK— Director
MICHAEL W. KLEMENS— Section Editor, *Catalogue of American Amphibians and Reptiles*
PAUL MOLER— Chair, Conservation Committee
EDWARD O. MOLL— Immediate Past-President and Chair, Long-Range Planning Committee
CRAIG E. NELSON— Chair, 1993 Local Committee
GEORGES PASTEUR— Editorial Board, *Journal of Herpetology*
ERIC M. RUNDQUIST— Chair, Regional Societies Liaison Committee
NORMAN J. SCOTT— Chair, Henri Seibert Awards Committee
DOUGLAS H. TAYLOR— Treasurer

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 1 August 1994 at its Annual Business Meeting.

Kennedy Student Award Committee Annual Report – 1994

The Kennedy Award Committee has completed its work for Volume 27 of the *Journal of Herpetology*. The Committee has selected "Maternal Brood Care by *Dendrobates pumilio*: A Frog that Feeds its Young" by Douglas G. Brust. Mr. Brust carried out this work as a doctoral candidate in the Section of Ecology and Evolutionary Biology of Cornell University. His present address is the College of Physicians and Surgeons at Columbia University, Box 509, 630 West 168th Street, New York, New York 10032, USA. F. Harvey Pough provided research direction as major professor.

Twelve manuscripts were in competition this year. The Committee noted the high quality of the submitted papers.



KEN R. MARION, Chair
Kennedy Student Award Committee.

Seibert Award Winners for 1994 Announced

The third annual Seibert Awards were presented at the 37th Annual Meeting of the SSAR in Athens, 28 July–1 August 1994. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). The awards recognized outstanding student presentations at the annual meeting.

The winners: Joseph H. K. Pechmann (Duke University and Savannah River Ecology Laboratory), First Prize ($250); Frank R. Hensley (University of Florida at Gainesville and Savannah River Ecology Laboratory), Second Prize ($150). Honorable Mention: Paul T. Andreadis (University of Tennessee at Knoxville); Bradley T. Braun (Lehigh University); S. B. Reichling (University of Memphis); Kevin C. Zipple (Cornell University).

The judges were Neil Ford, John Iverson, Fredric Janzen, Randall Krohmer, Charles R. Peterson, and Susan Walls.

SSAR Student Travel Awards Fundraiser Call For Donations

At the 1994 SSAR/HL meetings in Athens, Georgia, the newly formed SSAR Student Travel Awards Committee organized a frameable art silent auction to raise funds for students attending and presenting papers at an annual meeting. Because of the great success of the first silent auction (over $2000 raised), the Travel Awards Committee is pleased to announce the second frameable art silent auction to be held at the 1995 SSAR meeting in Boone, North Carolina. Many people attending the Athens meeting expressed an interest in donating an item to the silent auction. Items acceptable as a donation include: photos of your favorite study animal (or herpetologists!), line drawings, prints, paintings, or anything else that can be put into a frame, if not framed already. If you are interested in donating an item please contact *Dawn S. Wilson, Biology Dept., University of South Florida, Tampa, Florida 33620, USA; tel. (813) 974-9175; FAX (813) 974-3263; E-mail: WILSON@CHUMA.CAS.USF.EDU.*

SSAR Student Travel Award Donors

The SSAR Student Travel Awards Committee wishes to thank the following people for their donations to the 1994 SSAR frameable art silent auction held in Athens, Georgia: Kraig Adler, Ronald Altig, Patty Barber, Jonathan Campbell, David Cannatella, Martin Capron, David Chiszar, David Dennis, Dale Jackson, William Lamar, Ernie Liner, Linda Maxson, Roy McDiarmid, Margo McKnight, Don Moll, Henry Mushinsky, Alan Savitzky, David Scott, Richard Seigel, Adam Summers, Peg Summers, and Steve Werman.

SSAR Student Travel Awards Call For Applications

Ten SSAR Student Travel Awards of $200 each are available to undergraduate and graduate student members of the SSAR to help defray the cost of travel to the upcoming meeting in Boone, North Carolina. An applicant must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author of a paper or poster to be presented. An applicant must include in the application package:

1) a letter signed by his or her major advisor or department chair stating that he or she is currently an undergraduate or graduate student and that he or she is not completely funded for travel from another source;

2) an official copy of the poster or paper abstract to be presented;

3) a self-addressed, stamped envelope.

If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Travel Awards Committee are excluded from applying for a travel award. APPLICATIONS MUST BE POSTMARKED BY 15 MAY 1995. Award recipients will be notified by early June 1995 and award checks will be dispersed at the meeting. Send applications to: *Dawn S. Wilson, Department of Biology, University of South Florida, Tampa, Florida 33620, USA. For further information Wilson may be contacted at: Tel. (813) 974-9175, FAX (813) 974-3263; e-mail WILSON@CHUMA.CAS.USF.EDU.*

New Section Editors Named For *HR*

Owing to the increased number of "techniques" manuscripts submitted to *Herpetological Review*, a new section editorship has been established. Authors of techniques manuscripts should submit these directly to the new section editor: *Stephen D. Busack, Section Editor—Techniques, National Fish & Wildlife Forensics Laboratory, 1490 East Main Street, Ashland, Oregon 97520, USA.*

Additionally, the section editor for Natural History Notes (Amphibia), Randy Jennings, has resigned due to other commitments. The Editor and SSAR thank him for his efforts and wish him well. Natural History Notes concerning amphibians should be sent to the new section editor: *Charles W. Painter, Section Editor—Natural History Notes, Endangered Species Program, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.*

NEWSNOTES

The Canadian Association Of Herpetologists Invites New Members

The Canadian Association of Herpetologists is a scientific organization of professionals, students, and interested amateurs whose goals are to foster herpetological research and to aid communication between reseachers in Canada. Membership in CAH is open to all those whose work is concerned with the biology of amphibians and reptiles, particularly those who are located in Canada, who are working with Canadian populations, or who are interested in herpetology in Canada. The Association will celebrate its tenth anniversary in 1995. Its annual meeting is held in conjunction with an annual meeting of one of the three large North American herpetological societies, ASIH, HL, and/or SSAR and, in the tradition of the Association, business is held *after* the pleasure of an informal evening banquet. The Association is a part sponsor of the Canadian Declining Amphibian Populations Task Force and reports on its proceedings and progress through its publication, the *CAH Bulletin*.

HERPETOLOGY IN ARIZONA

Status, distribution, and conservation of Arizona herpetofauna

Seasonal (up to 9 months) and Limited (up to 3 years) appointments available

Salary range: $18,288-$27,810/year
Limited appointments include benefits

Send request for information to:
Jeff Howland
Nongame Branch
Arizona Game and Fish Department
2221 W. Greenway Road
Phoenix, Arizona 85023

The *CAH Bulletin* is produced twice each year and publishes articles, news, and reviews of interest to herpetologists in Canada. The *Bulletin* also publishes thesis abstracts of M.Sc.'s and Ph.D.'s completing research in Canadian herpetology. Reports submitted for publication may be in the form of short announcements or letters, or may be written as longer articles. Articles may be published in English or French. The *Bulletin* especially requests news about current research activities and recent publications, travel plans, new students, grants, awards, fellowships, new books, or book reviews, trivia, or concerns. Correspondence and submissions, preferably stored on a 3.5-inch floppy disc or sent by e-mail, should be addressed to the editor: *David M. Green, Redpath Museum, McGill University, 859 Sherbrooke St. W., Montreal, Quebec H3A 2K6 (Fax: 514-398-3185 • email: czdg@musica.mcgill.ca).*

Annual membership dues in CAH (in Canadian funds) are $10.00 (regular) or $5.00 (student, with proof of status) payable to the Canadian Association of Herpetologists. Membership requests should be sent to: *Dr. Patrick T. Gregory, Department of Biology, University of Victoria, Victoria, B.C., V8V 2Y2 Canada.*

Declining Amphibian Populations Task Force Update

The DAPTF office has been moved, from Corvallis, Oregon USA, to the United Kingdom (new address below). The new Chair is Ron Heyer and the new Executive Director is Tim Halliday. To contact the DAPTF or to be placed on the mailing list for their newsletter, *FROGLOG*, write to: *DAPTF, Department of Biology, The Open University, Walton Hall, Milton Keynes, MK7 6AA, United Kingdom.*

Southwestern Research Station Positions And Grants For 1995

VOLUNTEERS—Approximately 20 volunteer positions are open in 1995 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 15 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, AZ 85632 USA; telephone 602-558-2396.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192. Application due date: Feb. 15, 1995. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632 USA; telephone 602-558-2396.*

SEASONAL OFFICE ASSISTANT—Assist in operations of biological research station office and nature shop: taking reservations, answering phones, greeting guests, supervising volunteers, etc. Begin March 15, 1995, through September 1995. Five-day week; salary $190/wk, plus room (shared) and board. Applicant must be punctual, organized, enjoy people, and be interested in living in a remote setting (Chiricahua Mountains) and working with biological researchers. Biological training an asset. Call and send résumé to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA. Telephone and fax: 602-558-2396.*

MEETINGS

British Herpetological Society Meetings For 1995

The British Herpetological Society has released a preliminary timetable for meetings during 1995. Further details concerning time and venue for most of these meetings will be published in the BHS *Bulletin* as soon as they become available. Additional information concerning meetings or membership may be obtained by corresponding with: *The Secretary, British Herpetological Society, c/o Zoological Society of London, Regent's Park, London NW1 4RY, U.K.*

1. Herpetofauna Recorders' Meeting (4 February).
2. Herpetological Speakers Workshop, Birmingham (18 February).
3. Annual General Meeting, Birkbeck (18 March). Speakers include Lee Brady: "Leeches, malaria & cyclones: studying chameleons in Madagascar;" Ian Bride: "The welfare aspect to the retail pet trade in reptiles and amphibians;" and Mark Fisher: "Conservation through commercialisation."
4. Captive Breeding (Veterinary) Meeting (25 March).
5. Joint Conservation/Education Meeting (8–9 April).
6. Leapers & Creepers/visit to Beam Brook (Surrey) (mid-May).
7. Captive Breeding Meeting: Chelonia. Paul Eversfield (27 May).
8. Captive Breeding Meeting: Breeding reptiles commercially for the trade (29 July).
9. October General Meeting, Birkbeck College (14 October). Speakers include Stephen Divers: "Mortality and disease of imported royal pythons;" Rob Quest: "Reptile imports;" and Mary Swan: "Results from the National Amphibian Survey."
10. Captive Breeding Meeting: Breeding monitor lizards (7 or 28 October).
11. Research Meeting, Birkbeck (2 December).

LEGISLATION & CONSERVATION ALERT

U.S.A.: Department of the Interior: The U.S. Fish and Wildlife Service has proposed that the Barton Springs salamander (*Eurycea sosorum*) be listed as Endangered. The Barton Springs salamander is entirely aquatic and lives in a complex of karst springs that are owned by the City of Austin, Texas. Although several of the springs are used for recreational swimming, this activity seems to be compatible with the persistence of the salamanders. However, the major concern to *E. sosorum*, the Barton Springs habitat, and the entire Edwards Aquifer is water contamination through chemical spills, urban runoff, and development (Endangered Species Tech. Bull. Vol. XIX, No. 3, 1994).

México: The Government of México has produced a list of endangered, threatened, and rare flora and fauna (Diario Oficial de la Federacion, Tomo CDLXXXVIII No. 10, 16 May 1994). The list contains 477 species and subspecies of reptiles and 139 species and subspecies of amphibians. For further information, interested persons should contact *Dr. Oscar Flores Villela, Museo de Zoologia, Universidad Nacional Autonoma de México, Apartado Postal 70-399, México D.F. 04510 México.*

KURT A. BUHLMANN
SSAR Conservation Committee.

LETTERS TO THE EDITOR

Dear Editor:

Back in October of 1990 John Zyla and I published a little note on wood turtles from the Atlantic Coastal Plain along Maryland's western shore (The Maryland Naturalist 33[1–2]:37–41). The text was four paragraphs long, included a photograph and one map, and listed twelve records for *Clemmys insculpta* from Anne Arundel and Prince Georges Counties. It stated simply that *C. insculpta* occurred locally on the Coastal Plain along the western side of the Chesapeake Bay, and that the presence of a newly hatched individual provided evidence of recent reproduction. Robert Miller subsequently took considerable exception to that short paper and published a lengthy critique in this journal (1993. Herpetol. Rev. 24:90–93). When I first read Miller's critique of our note I thought that he was discussing a different paper. He seems to have gotten much more from our article than we put into it, and after reading it again, I still do not know what raised Miller's ire to the level expressed in his discussion. However, since he has introduced some misconceptions into the literature, stated or implied numerous things that adversely reflect on us or other local naturalists, and attacked the Natural History Society of Maryland, which publishes *The Maryland Naturalist*, I feel compelled to offer some rebuttal.

Miller's criticism of our note centers around the use of what he considers to be "undocumented" records to establish the presence of this turtle in an area of Maryland where only a few scattered reports previously existed. In doing this he discusses just about every wood turtle that has ever been reported from east-central Maryland. While this is interesting, absolutely none of it is new information, and very little, if any, has anything to do with the argument that he attempts to make. Miller even cites additional records that, by his own admission, could have been used to support our records. However, all this aside, the major points that come from his discussion are that he apparently doubts the records that we reported (without contacting the persons who gave the reports to us, all of whom were identified in our paper), doubts several records published by Dr. Carl Ernst, and feels intuitively that this turtle can not occur where we report it.

Frankly, I am not sure why Miller finds it so surprising that wood turtles might encroach onto the Maryland Coastal Plain, because that's exactly what they do everywhere else. Carl Ernst (pers. comm.) is aware of several records for this species on the Virginia Coastal Plain in Alexandria and Fairfax Counties, one as far down as Fort Belvoir near the Potomac River. In New Jersey there are numerous records along the Piedmont/Coastal Plain boundary and Robert Zappalorti (pers. comm.) knows of several sites where they have penetrated onto the Coastal Plain in Gloucester and Burlington Counties, and has under study a location where this species actually occurs on the fringe of the Pine Barrens in Ocean County. The Ocean County record represents over fifteen marked turtles, including juveniles. Roger Conant mentioned to me that he also knows of New Jersey Coastal Plain records. Although there are only two known Delaware localities, one is right at the edge of the Piedmont/Coastal Plain boundary at Brandywine Creek State Park, and the other is clearly on the Coastal Plain just east of Newark (Jim White, pers. comm.). Considering this, I would be more surprised to find that *C. insculpta* did not occur on the Maryland Coastal Plain.

Miller takes us to task for not explaining what our records mean. John Zyla and I did not discuss this because we don't know what they mean, and neither does Miller. In his first paragraph, Miller assumes that we consider all the records from the Maryland Coastal Plain to represent natural occurrences. This is incorrect and is not supported by anything in our note. However, such a large number of turtles from that area, including young individuals and hatchlings, suggests to me that they should be acknowledged as elements of the local biota, whether they arrived on their own or were introduced. Miller's lengthy discussion is apparently intended to provide an answer to his question by determining if the turtles represent natural occurrences or recent introductions, or show that there is no basis for their existence by demonstrating that either we and the other naturalists who told us about these turtles misidentified the animals in question or were otherwise in error. After carefully reading his opinion several times, I must conclude that he succeeds in shedding no more light on this than we did. What Miller has done is take a great deal of space to show that there is very little historic evidence of the presence of wood turtles in this area. John Zyla and I knew that when we started; that's precisely why we wrote our note.

Miller devotes half a page to our mention of an historic record from Maryland's eastern shore that was reported by John Norman and discussed by Clyde Reed, a professional botanist with diverse interests in natural history. Miller attempts to prove that Reed's opinion of the zoogeographic significance of Norman's turtle was unreasonable, and attacks Reed's other early herp papers to support his argument. Miller is correct in his assertion that most herpetologists tend to ignore that record. However, local researchers in other disciplines (ichthyology, invertebrate zoology, botany) have continued to be intrigued by it. The central and lower Delmarva includes several good examples of "Piedmont species" (the mottled sculpin, black-nosed dace, and shield darter for example), that show disjunct populations apparently representing Pleistocene relicts. For some of these this is the only place in the species' range where they occur on the Atlantic Coastal Plain. These fishes, incidentally, consistently occur in streams inhabited by wood turtles in Maryland and adjacent Pennsylvania. Considering this, I feel that it would be shortsighted to disregard Norman's specimen without knowing much more about the distribution of various species on the Delmarva. It may also be worth mentioning that the past decade or so has seen the discovery of a number of interesting species on the

Delmarva, some of which are large and/or showy (barking treefrog, curly grass fern, Atamasco lily, pond spice, Hirst's panic grass, etc.), as well as significant additions to the "known" distribution of others (tiger salamander, bog turtle, red-belly water snake). Clearly, we do not know nearly as much about the distribution of plants and animals on the Delmarva as Miller thinks we do.

Twenty thousand years ago most of the wood turtle's present range was beneath glacial ice, and much of the rest was tundra or boreal forest. I consider it unlikely that wood turtles were present in the northeast at that time. Instead, they, like just about everything else from this region, were probably forced southward (there are fossil records from Georgia and Tennessee). The Piedmont fishes now occupying disjunct habitats on Maryland's lower eastern shore moved down the ancestral Susquehanna paleochannel onto the Delmarva, and possibly the adjacent outer Coastal Plain (now the Continental Shelf). Although there is no fossil record to support it, I consider it possible that the wood turtle did the same thing. When the Laurentide ice sheet began to recede about 18,000 ybp those displaced populations would have again moved north and eventually came to occupy their present ranges. The movement of these species through the Delmarva, which could have happened several times as the glaciers waxed and waned, would have happened well before rising sea levels fueled by melting of the Laurentide ice created the modern Chesapeake Bay, which happened as recently as 5,000 ybp. The Piedmont fishes still occupy scattered, disjunct populations as relicts of these previous range adjustments. Like these fishes, a relict population of wood turtles could have done the same and may have survived until recently. This cannot be resolved at the present time, but the idea should not be disregarded quite yet.

I also take issue with Miller's statement that "Reptile distributions in Maryland were well known long before Reed's 1958 article...." McCauley's publication, which Miller cites in support of his remark, is just about all there was before Conant published the first edition of his field guide in 1957. McCauley, whose work I respect greatly, had only eleven verified records for this turtle, virtually none of which was from the eastern half of its range in Maryland. Conant's book, which did so much to clarify distributions, appeared just before Reed's publication, and may not even have been available when his paper went to the printer. In 1958 I was actively involved in local field work. I, and everyone else on the scene at that time, was struggling to understand the distribution of various species in this area, and no one had a clear understanding of what was going on. Miller's statements about Dr. Reed and his many "egregious errors," are unfair and show a remarkable lack of understanding of the difficulties under which amateur herpetologists worked 35 years ago. I suggest that Miller attempt to demonstrate a bit of sensitivity when he moves to criticize those who worked in his field before he was born.

I am not sure what Miller means when he says that *C. insculpta* is a "montane" turtle, but whatever he intended to convey, the statement is absurd. A brief look at any published range map for this species shows that it clearly ranges widely into lowland areas on the Piedmont east of the Appalachians, and westward into the Central Lowlands around the Great Lakes where it occupies the Drift Plains and Hill Prairies of Wisconsin and eastern Minnesota. Further, his contention that its "range encompasses very little of the piedmont, regardless of how liberally one accepts locality records" is equally ridiculous. Numerous records on the Piedmont Physiographic Province are documented in the published herp surveys for Maryland, Pennsylvania, and Virginia, and biologists, naturalists, and herpetologists in this area are quite familiar with this turtle. It is typically found along floodplains and streams throughout the Maryland Piedmont. Miller may not be aware of these reports, but there are dozens of them, dating back decades.

Miller does review the literature that documents the repeated observation of this species on and around Plummers Island, near the edge of the Piedmont/Coastal Plain boundary just above metropolitan Washington, D.C. This obviously is not a turtle that is of "debatable occurrence" in that area. Another interesting record is provided by a sizable population of wood turtles in northeastern Harford County that has been under study by Bob Chance (pers. comm.) for over a decade. Chance's population, which is doing well, is actually on the Coastal Plain, but very close to the edge of the Piedmont. In my opinion, the presence of the bonafide Piedmont wood turtle records given in Herb Harris's Maryland Distributional Survey (eighteen records, more than all other physiographic provinces combined) and the literature cited by Miller, and at least these two areas way over near the eastern edge of the Piedmont where repeated occurrences have been documented (three areas if you are inclined to accept the turtles reported by Zyla and me), identifies the wood turtle as a legitimate member of Maryland's Piedmont herpetofauna.

Having discussed various local finds with Miller on numerous occasions, I am well aware that he is hesitant to accept reports not supported by voucher specimens. However, over the years I have observed a lot of wood turtles in Maryland (my field notes record eleven individuals on the Piedmont alone), and discussion with other knowledgeable persons (amateur herpetologists, amateur and professional naturalists, foresters, wildlife and fisheries biologists, science teachers, park rangers, etc.) shows that many others have made similar observations. Although Miller would not accept these reports as "records" they are none the less useful in determining where this species occurs and where it may not. By eliminating this information from his data base, Miller limits himself to the handful of existing preserved specimens. A Maryland range map drawn by Miller would be well documented, but I believe that one drawn by me would better reflect the local distribution of this turtle.

Miller tends to gather incomplete bits of information and use them to support his contentions as if they were significant. For instance, he "disregards" the Elvaton record because Clyde Prince did not publish on it, and it is not mentioned in the Prince notebooks that were deposited at Towson State University after Clyde's untimely death. Unfortunately, Miller neglected to mention that Clyde Prince never published much of anything. He also kept very sporadic notes, all of which are not at TSU. I still have several of his notebooks that were given to me by Barbara Prince. Clyde was a close personal friend and we talked about reptiles often. He was excited by the Elvaton turtle, discussed it with me in detail, and even called me long distance to tell me that it had been given to him. He did consider it significant, and I resent Miller's inference that he did not. I doubt that he ever spoke to Clyde. I was aware of Clyde's record for over a decade without making much of it. For the same reason, I never considered the DOR found by me near Annapolis in 1971 to be more than mildly interesting until John Zyla and I pooled our information and realized that there were too many records from the area to write off as "releases" or "escapes."

The Prince turtle brings me to another point that I consider important. Miller says emphatically that "no reliance can be placed" on that record. Elsewhere in his critique he states that records from Carl Ernst's published range map "cannot be allowed." Just because Miller writes something down and it gets published does not make it gospel. The readers of your journal would probably be better served if authors who state opinions would use words that imply opinion, such as "I believe," "I feel," "in my opinion," or "I suggest that." Unless the international herpetological community has elected Miller as their spokesperson, it is not for him to disallow any record. When he publishes his opus on the Maryland fauna, he may decide to disregard them. However, the decision to accept or reject a record should be made by each of us, individually.

Toward the end of his diatribe Miller gets around to the issue of "documentation." This is a real sore point that he and I have discussed many times. He clearly feels that records are unreliable unless they are based on preserved material in a recognized collection. I feel that this is a reasonable position when a species is likely to be misidentified. However, with a species like the wood turtle, which any good naturalist with Conant and Collins' field guide can identify reliably, I am willing to accept a sight record. In this time of concern for animal rights, increasing information about the fragile nature of *Clemmys* populations, and tightening non-game species regulations, I consider the collection of wood turtles to be unacceptable. The simple fact here is that John Zyla and I presented records for twelve specimens, some of which we had seen personally, some that were seen by competent local naturalists, and three of which were still alive in captivity. Miller has decided that these records are unreliable. John and I disagree. I would also like to state that the records reported to us by others were accepted only after John Zyla and I were convinced that the persons in question knew what they were talking about. We did reject several reports that we considered questionable.

I found it very interesting that Miller not only cited Austin Clark's paper on wood turtles from the Plummers Island vicinity, but gave it considerable credibility. It's interesting because Clark's paper is virtually identical to ours. Clark presented information on twelve wood turtles from an area near the eastern edge of the Piedmont, where they had been rarely reported previously. Of his records, most were what Miller would consider unsubstantiated reports from local naturalists, three are preserved at the USNM (three of ours were still alive in captivity at nature centers), and one was documented by a photograph that Clark saw but did not publish (we published a photograph of one of the turtles listed by us). I assume that Miller accepts Clark's paper while rejecting ours because the intervening years have resulted in sporadic reports of additional turtles from that area, and it is within what he considers to be the normal range of *C. insculpta*. Apparently, Miller isn't willing to wait to see if our data stand the test of time equally well. Incidentally, since our note appeared I have received reports of several additional wood turtles from this portion of the Maryland Coastal Plain.

Miller strongly criticizes our use of two Coastal Plain localities shown by Carl Ernst on the map included with his Catalogue account for *Clemmys insculpta*. We discussed those records with Dr. Ernst and have no hesitancy in accepting them, contrary to Miller's determination that "they cannot be allowed." Our plotting of those dots was not as haphazard as Miller implies. We scanned Carl's original map into a competent GIS system then enlarged it to overlay previously digitized state maps with county boundaries. Since we found a pretty good fit between Carl's map and several of those in the system, I believe that the dots are about where Carl put them. If Miller's implication is that Carl Ernst did not have good records when he prepared his map, or that he somehow mis-mapped them, I'm sorry, but we disagree. As for Miller's charge that in plotting Ernst's localities we are guilty of "inventing a county record," who cares? We are attempting to understand the distribution of an animal and, since that has nothing to do with geopolitical boundaries, I consider haggling over county records to be a total waste of effort.

The part of Miller's discussion that I find perhaps most objectionable is his criticism of the journal in which the note in question was published, *The Maryland Naturalist*. I do edit that journal, and can state unequivocally that every paper published there is peer reviewed, and that the few that I have published there were scrutinized more closely than any others. Miller knows all about this editorial policy because just before he wrote his critique of our note he submitted a manuscript that was subsequently withdrawn because he would not accept several reasonable recommendations that were made by reviewers. Since Miller understands this editorial policy and has first hand experience with our peer review process, his statements represent more than a misconception on his part. The Natural History Society of Maryland is a volunteer organization with a sixty-three year history. Throughout that time it has worked to support herpetology and natural history in Maryland with a considerable degree of professionalism and success. Miller's comments about that organization are unfair.

Toward the end of his critique, Miller makes a very informative statement when he writes, "I find it impossible to accept that a turtle as large and conspicuous as *Clemmys insculpta* could be as common (i.e., naturally occurring) in the suburbs of Baltimore, Washington, and Annapolis as Norden and Zyla indicate, yet somehow go unnoticed until recently." Basically, he is saying that he *can not* accept the records that we reported, and *would not* believe them no matter how many there were. This is hardly an objective approach to interpreting new data, and *Herpetological Review* does a disservice to herpetology by validating it. If we are ever to really understand the detailed local distribution of reptiles, we need more herpetologists with the ability to consider each and every record with an unbiased view, not researchers who approach data with preconceived certainty that it must somehow be false.

Second Update On The List Of Amphibians And Reptiles Known From Honduras

A decade has transpired since Wilson (1983) provided a listing of the amphibians and reptiles known at the time from the Central American country of Honduras. In the interim, research has continued apace, resulting in the addition of a sizeable number of taxa to the herpetofauna, either from range extensions or described as new to science. In addition, for this listing, we have added the marine turtles that visit the shores of Honduras, as well as the reptiles known to occur on the Swan Islands and the Honduran portion of the Miskito Keys. As of this writing, then, the total number of Honduran amphibian and reptilian species is 277, up from the 208 species included on the 1983 list. The increase of 69 taxa involved the addition of 73 species and the deletion of four (these include: *Bolitoglossa schmidti*, a synonym of *B. dofleini*, McCranie and Wilson, ms.; *Bufo cavifrons*, based on misidentified *B. valliceps*, McCranie and Wilson, ms.; *Eleutherodactylus gollmeri*, shown not to occur in Honduras by Savage 1987 [the specimens listed under this name by Meyer and Wilson 1971, represent three species]; and *Urotheca euryzonus*, shown not to occur in Honduras by Savage and Crother 1989, and Wilson, McCranie, and Espinal, ms.). The 73 species added to the 1983 list include one caecilian (status clarified by Nussbaum 1988), seven salamanders (six new to science, one range extension), 28 anurans (14 new to science, 13 range extensions, and one clarification of status [*Eleutherodactylus rostralis* by Savage 1987]), seven turtles (including six marine species not included in the 1983 list and one inclusion based on a

questionable record [*Rhinoclemmys areolata*]), 19 lizards (five new to science, five resident on the Swan Islands or Miskito Keys, seven range extensions [that for *Laemanctus serratus* is suspect, inasmuch as it is likely based on specimens collected by an animal dealer], and two reidentifications), and 11 snakes (one new to science, one resident in the Swan Islands, and nine range extensions). In total, the taxa added to the herpetofauna of Honduras include two due to clarification of their status, one based on a questionable record, six marine species, six resident on the Swan Islands or Miskito Keys, two reidentifications, 30 range extensions, and 26 new to science. Addition of the 56 taxa in the last two categories has occasioned a 27% increase in the size of the herpetofauna from that listed by Wilson (1983). We have not included the taxon *Corallus annulatus*, reported by Henderson (1993), inasmuch as the provenance of the specimens is very much in doubt, due to their collection for commercial dealers.

As with the previous paper (Wilson 1983), the species are listed in alphabetical order under each order. In addition, each name is followed by a parenthetically-enclosed number referring to a numbered reference in the Literature Cited section in which that species was reported as occurring in Honduras.

ORDER GYMNOPHIONA (3 species)

Dermophis mexicanus (29)
Gymnopis multiplicata (29)
Gymnopis syntrema (31)

ORDER CAUDATA (17 species)

Bolitoglossa carri (21)
Bolitoglossa celaque (21)
Bolitoglossa conanti (21)
Bolitoglossa dofleini (29)
Bolitoglossa dunni (29; see reference 21)
Bolitoglossa mexicana (29)
Bolitoglossa occidentalis (29)
Bolitoglossa rufescens (29)
Bolitoglossa striatula (29)
Bolitoglossa sp. 1 (Cortés: McCranie and Wilson, ms.)
Bolitoglossa sp. 2 (Yoro: McCranie and Wilson, ms.)
Nototriton barbouri (29, as *Chiropterotriton barbouri*)
Nototriton nasalis (29, as *Chiropterotriton nasalis*)
Oedipina cyclocauda (29)
Oedipina gephyra (26)
Oedipina ignea (46)
Oedipina stuarti (29)

ORDER ANURA (69 species)

Agalychnis callidryas (29)
Agalychnis moreleti (29)
Agalychnis saltator (14)
Anotheca spinosa (14)
Atelophrymiscus chrysophorus (24)
Bufo coccifer (29)
Bufo haematiticus (3)
Bufo luetkeni (29)
Bufo marinus (29)
Bufo valliceps (29)
Cochranella albomaculata (33, as *Centrolenella albomaculata*)
Duellmanohyla salvavida (19, as *Hyla salvavida*)
Duellmanohyla soralia (45, as *Hyla soralia*)
Eleutherodactylus anciano (39)
Eleutherodactylus aurilegulus (39)
Eleutherodactylus biporcatus (29)
Eleutherodactylus bransfordi (36)
Eleutherodactylus chac (37)
Eleutherodactylus chrysozetetes (16)
Eleutherodactylus cruzi (16)
Eleutherodactylus fitzingeri (14)
Eleutherodactylus laticeps (29; see reference 37)
Eleutherodactylus merendonensis (29)
Eleutherodactylus milesi (29)
Eleutherodactylus mimus (29)
Eleutherodactylus noblei (29)
Eleutherodactylus rhodopis (37)
Eleutherodactylus ridens (29)
Eleutherodactylus rostralis (37)
Eleutherodactylus rugulosus (29)
Gastrophryne elegans (29)
Hyalinobatrachium fleischmanni (29, as *Centrolenella fleischmanni*)
Hyalinobatrachium pulveratum (14)
Hyla bromeliacia (29, as *Hyla bromeliacea*)
Hyla catracha (35)
Hyla ebraccata (4)
Hyla insolita (27)
Hyla loquax (29)
Hyla microcephala (29)
Hyla picta (29)
Hyla salvaje (48)
Hypopachus barberi (50)
Hypopachus variolosus (29)
Leptodactylus labialis (29)
Leptodactylus melanonotus (29)
Leptodactylus pentadactylus (29)
Leptodactylus silvanimbus (23)
Phrynohyas venulosa (29)
Physalaemus pustulosus (29)
Plectrohyla chrysopleura (47)
Plectrohyla dasypus (17)
Plectrohyla glandulosa (49)
Plectrohyla guatemalensis (29)
Plectrohyla hartwegi (7)
Plectrohyla matudai (18)
Plectrohyla teuchestes (7)
Ptychohyla hypomykter (22)
Ptychohyla salvadorensis (29, as *Hyla salvadorensis*)
Ptychohyla spinipollex (29; see reference 22)
Rana berlandieri (29, as *Rana pipiens*)
Rana maculata (29, as *Rana macroglossa*)
Rana vaillanti (29, as *Rana palmipes*)
Rana warszewitschi (29, as *Rana warschewitschi*)
Rhinophrynus dorsalis (29)
Scinax staufferi (29, as *Hyla staufferi*)
Smilisca baudini (29)
Smilisca phaeota (29)
Smilisca sordida (42)
Triprion petasatus (50)

ORDER TESTUDINES (16 species)

Caretta caretta (12)
Chelonia agassizi (12)
Chelonia mydas (12)
Chelydra serpentina (30)
Dermatemys mawei (30)
Dermochelys coriacea (12)
Eretmochelys imbricata (12)
Kinosternon leucostomum (30)
Kinosternon scorpioides (30)
Lepidochelys olivacea (12)
Rhinoclemmys annulata (30)
Rhinoclemmys areolata (8; also see reference 34)
Rhinoclemmys funerea (30)
Rhinoclemmys pulcherrima (30)

Staurotypus triporcatus (30)
Trachemys scripta (30, as *Chrysemys ornata*)

ORDER CROCODILIA (2 species)

Caiman crocodilus (30)
Crocodylus acutus (30)

ORDER SAURIA (69 species)

Abronia salvadorensis (50, as *Abronia montecristoi*; see reference 2)
Ameiva ameiva (40)
Ameiva festiva (30)
Ameiva undulata (30)
Anolis allisoni (30)
Aristelliger georgeensis (1)
Aristelliger praesignis (40)
Basiliscus plumifrons (30)
Basiliscus vittatus (30)
Celestus bivittatus (50)
Celestus montanus (30)
Celestus sp. (Yoro: McCranie and Wilson, ms.)
Cnemidophorus deppei (30)
Cnemidophorus lemniscatus (30)
Cnemidophorus motaguae (30)
Coleonyx mitratus (30)
Corytophanes cristatus (30)
Ctenosaura bakeri (30, as *Enyaliosaurus bakeri*; see reference 6)
Ctenosaura oedirhina (6)
Ctenosaura palearis (30, as *Enyaliosaurus palearis*)
Ctenosaura quinquecarinata (30, as *Enyaliosaurus quinquecarinatus*)
Ctenosaura similis (30)
Eumeces managuae (5)
Eumeces sumichrasti (30)
Gonatodes albogularis (30)
Gymnophthalmus speciosus (30)
Iguana iguana (30)
Laemanctus longipes (30)
Laemanctus serratus (13)
Leiocephalus carinatus (40)
Lepidophyma flavimaculatum (30)
Mabuya unimarginata (30, as *Mabuya mabouya*)
Mesaspis moreleti (30, as *Barisia moreleti*)
Norops amplisquamosus (25)
Norops biporcatus (30, as *Anolis biporcatus*)
Norops capito (30, as *Anolis capito*)
Norops crassulus (30, as *Anolis crassulus*)
Norops cupreus (30, as *Anolis cupreus*)
Norops humilis (30, as *Anolis humilis*)
Norops johnmeyeri (44, as *Anolis johnmeyeri*)
Norops laeviventris (30, as *Anolis laeviventris*)
Norops lemurinus (30, as *Anolis lemurinus*)
Norops limifrons (30, as *Anolis limifrons*; see reference 46)
Norops loveridgei (30, as *Anolis loveridgei*)
Norops oxylophus (14)
Norops pentaprion (30, as *Anolis pentaprion*)
Norops petersi (18)
Norops pijolense (28)
Norops purpurgularis (15)
Norops rodriguezi (46)
Norops sagrei (30, as *Anolis sagrei*)
Norops sericeus (30, as *Anolis sericeus*)
Norops sminthus (30, as *Anolis sminthus*)
Norops tropidonotus (30, as *Anolis tropidonotus*)
Norops uniformis (46)
Phyllodactylus palmeus (30)
Phyllodactylus tuberculosus (30)
Polychrus gutturosus (30)
Sceloporus malachiticus (30)
Sceloporus squamosus (30)
Sceloporus variabilis (30)
Sphaerodactylus dunni (30)
Sphaerodactylus glaucus (9)
Sphaerodactylus millepunctatus (30, as *Sphaerodactylus continentalis*)
Sphaerodactylus notatus (40)
Sphaerodactylus rosaurae (30)
Sphenomorphus cherriei (30, as *Scincella cherriei*)
Sphenomorphus incertus (46)
Thecadactylus rapicauda (30)

ORDER SERPENTES (101 species)

Adelphicos quadrivirgatus (51)
Agkistrodon bilineatus (51)
Alsophis cantherigerus (40)
Amastridium veliferum (51)
Atropoides nummifer (51, as *Bothrops nummifera*)
Boa constrictor (51)
Bothriechis bicolor (51, as *Bothrops bicolor*)
Bothriechis marchi (51, as *Bothrops marchi*)
Bothriechis schlegeli (51, as *Bothrops schlegeli*)
Bothrops asper (51, as *Bothrops atrox*)
Cerrophidion godmani (51, as *Bothrops godmani*)
Chironius grandisquamis (51)
Clelia clelia (51)
Coniophanes bipunctatus (51)
Coniophanes fissidens (51)
Coniophanes imperialis (51)
Coniophanes piceivittis (51)
Conophis lineatus (51)
Crisantophis nevermanni (51)
Crotalus durissus (51)
Dendrophidion nuchale (51, as *Dendrophidion clarki*)
Dendrophidion percarinatum (51)
Dipsas bicolor (51)
Dryadophis dorsalis (51)
Dryadophis melanolomus (51)
Drymarchon corais (51)
Drymobius cloroticus (51)
Drymobius margaritiferus (51)
Drymobius melanotropis (51)
Elaphe flavirufa (51)
Enulius flavitorques (51)
Erythrolamprus mimus (51)
Ficimia publia (51)
Geophis fulvoguttatus (20)
Geophis hoffmanni (51)
Hydromorphus concolor (51)
Imantodes cenchoa (51)
Imantodes gemmistratus (51)
Imantodes inornatus (51)
Lampropeltis triangulum (51)
Leptodeira annulata (51)
Leptodeira nigrofasciata (51)
Leptodeira septentrionalis (51)
Leptodrymus pulcherrimus (51)
Leptophis ahaetulla (51)
Leptophis mexicanus (51)
Leptophis modestus (51)
Leptophis nebulosus (51)
Leptotyphlops goudoti (51)
Loxocemus bicolor (51)
Masticophis mentovarius (51)
Micrurus alleni (14)
Micrurus browni (20)
Micrurus diastema (51)

Micrurus nigrocinctus (51)
Micrurus ruatanus (51)
Ninia sp. (51, as *Ninia atrata*; McCranie and Wilson, ms.)
Ninia diademata (51)
Ninia sebae (51)
Nothopsis rugosus (32)
Oxybelis aeneus (51)
Oxybelis brevirostris (51)
Oxybelis fulgidus (51)
Oxyrhopus petola (51)
Pelamis platurus (51)

Rotenone Hazards To Amphibians And Reptiles

Declining amphibian populations throughout the world have been the focus of much recent attention (Barinaga 1990; Brown 1990; Pechmann et al. 1991). One reason suggested for this apparent decline is poisoning by pesticides and pollutants (Blaustein and Wake 1990; Bury and Whelan 1984; Honegger 1978). In a recent review of the status and needs for assessing effects of pesticides on amphibians and reptiles, Hall and Henry (1992) pointed out that evaluating risk of chemical hazards for amphibians and reptiles is complicated by their taxonomic, ecological, physiological, and geographic diversities. Interestingly, tadpoles (*Rana* spp.) and adult lizards (*Anolis carolinensis*) currently are the only species for which pre-registration testing of chemicals for acute lethal toxicity has been considered. Similarly, no information is available for the majority of environmental chemicals as hazards to amphibians or reptiles. Further, the standard toxicological tests for homeothermic vertebrates and for fish may not be useful for or protective of the herpetofauna.

Rotenone, also known as derris or cubé root, is a natural chemical compound extracted from the stems and roots of particular tropical plants (bean family Leguminosae). The principal use of rotenone is as an insecticide or piscicide. For centuries, natives in the tropics have used rotenone for stunning and killing fish. Rotenone now is a commonly used pesticide in North America and has been used in fish management since 1934. Because of its effectiveness as a fish toxicant, rotenone is widely used to sample fish populations or to improve fisheries by removing or reducing populations of undesired or nuisance fish species (Lennon et al. 1970; Schnick 1974; Sigler and Sigler 1990; Sousa et al. 1988). However, recent reviews of the amphibian and reptile toxicological literature (Devillers and Exbrayat 1992; Hall and Henry 1992) did not address the potential hazards of rotenone, while a Canadian technical report (Power et al. 1989) provided only a tabular review of acute toxicity and one field study which dealt primarily with benthic invertebrates (Burress 1982). Therefore, the objective of this paper is to evaluate the toxicity of rotenone to amphibian and reptile populations through review of the available literature, and to provide information which may be useful to resource managers in evaluating the risk of rotenone applications to the aquatic herpetofauna.

Although practically insoluble in water (0.2 mg/L), rotenone is quite lipid-soluble (log P 4.26). Rotenone also is an unstable compound that is non-persistent and essentially does not bioaccumulate. Degradation is affected by temperature, light, oxygen, and pH. Other factors affecting the degradation rate, and therefore reducing toxicity, include presence of organic debris, turbidity, lake shape and depth, dilution by inlets and runoff, and the dosage used (Sousa et al. 1988). The half-life of a Noxfish formulation of rotenone (5% w/w) is 10.3 days in cold water (32°–41°F) and 0.94 days in warm water (73°–81°F). Decomposition follows a first-order decay curve (Gilderhus et al. 1988).

Rotenone is applied as a wettable paste/powder or as an emulsifiable spray concentrate containing approximately 5% rotenone. Common application methods include using drip stations or sprayers and pumping through hoses into the propeller wash of power boats. In some cases, aerial applications are used. Treatments with 5% rotenone usually range from 0.5 ppm to 5.0 ppm, with a typical treatment rate of 2 ppm (Sousa et al. 1988).

Toxicological/biochemical studies with fish indicate that major sites of bioconcentration of rotenone residues are liver, bile, gills, brain, and heart. Biliary excretion is the major elimination route for rotenone and rotenoid residues (Gingerich 1986; Gingerich and Rach 1985; Rach and Gingerich 1986). In the liver of fish, rotenone is oxidized to less toxic forms primarily by a

microsomal monooxygenase enzyme system, cytochrome P450. Interestingly, polycyclic aromatic hydrocarbons (PAH's) are capable of inducing certain hepatic microsomal monooxygenases (MO). Because of widespread use/presence of PAH's in the aquatic environment, hepatic MO's of fish in polluted waters may be altered and the toxicity of xenobiotics (such as rotenone) affected by their activities. Piperonyl butoxide, a common synergist in rotenone formulations (e.g., Nusyn-Noxfish), has been shown to inhibit the hepatic microsomal oxidation of rotenone while concomitantly causing enzyme induction (see Erickson et al. 1992). Similarly, polychlorinated biphenyl (PCB) residues in fish may increase their sensitivity to rotenone treatment (Bills et al. 1981). And PCB's are known to act as a synergist for carbamate insecticides (Plapp 1972) and other environmental contaminants (Bills et al. 1977). In addition, Fabacher and Chambers (1972) suggested that rotenone resistant mosquitofish were the result of increased levels of mixed-function oxidase enzymes. Reports for fish clearly indicate that tissue distribution and rates of uptake, detoxification and elimination influence sensitivity of fish to rotenone and suggest the potential effects of other environmental chemical contaminants as additive or possibly synergistic.

The site of toxic action of rotenone is the electron transport system in the mitochondria where reoxidation of reduced nicotinamide adenine dinucleotide by NADH-dehydrogenase is blocked (Horgan et al. 1968; Lindahl and Oberg 1961). Therefore, death is caused by oxygen deprivation. Rotenone may be neutralized by potassium permanganate or chlorine, or toxicity may be reversed by placing affected fish in a solution of methylene blue (Sousa et al. 1988).

Rotenone is known to be relatively harmless to plants and mammals, but very toxic to insects, other invertebrates, and fish. Fish are particularly susceptible to rotenone because of partitioning across the gills and inability of fish to avoid exposure. Being lipid-soluble, rotenone will be absorbed into both skin and respiratory membranes, but skin may provide more of a barrier due to differences in diffusion distances. Although basically a broad spectrum fish toxicant, rotenone is reported to have selectively killed a few species of fish (Sigler and Sigler 1990; Sousa et al. 1988). As reported by Marking and Bills (1976), the 24-hour acute toxicity (LC50) of rotenone for fish varied from 0.0165 mg/L for walleye (*Stizostedion vitreum*) to 0.665 mg/L Noxfish for black bullhead (*Ictalurus melas*). Further, a general trend was apparent in that salmonids were most sensitive, centrarchids were of intermediate sensitivity, and ictalurids were least sensitive.

Because various formulations of rotenone differ in actual percentage rotenone contained, care should be taken in interpretation of toxicity data from studies involving different formulations. In addition to unformulated technical rotenone, several commercial formulations have been utilized, including the following: Noxfish, an emulsifiable concentrate containing 5% rotenone; Pro-Noxfish, a synergized emulsifiable concentrate containing 2.5% rotenone and 2.5% sulfoxide synergist; Dri-Noxfish, a dispersible powder containing 20% rotenone; Chem-Fish Special, an emulsifiable concentrate containing 5% rotenone; and Nusyn-Noxfish, a emulsifiable concentrate containing 2.5% rotenone synergized with 2.5% piperonyl butoxide. In toxicity reports for amphibians, several studies utilized unformulated technical rotenone while others included commercial formulations of rotenone as Noxfish, Pro-Noxfish and Dri-Noxfish (see Table 1 and Burress 1982). For purposes of this review to compensate for different formulations used and to allow for better comparisons among studies, a calculated value as a standard has been included in Table 1 as a supplement to the original LC50 values reported in the scientific literature. This standardized value was calculated by multiplying the percent of rotenone contained in a given formulation by the LC50 reported for that formulation. In addition, temperature, pH, alkalinity, flow rate, turbidity, and physical conditions are all factors which might affect the toxicity of rotenone (Schnick 1974); such values are included in Table 1 as available.

Relative to amphibians, a fisheries management report (California Department of Fish and Game 1985) stated that treatment with 2 mg/L rotenone formulation (Noxfish) with LC50 values ranging from 5.8 mg/L (96-hour) to 24.0 mg/L (24-hour) would not seriously affect adult frogs and other amphibians. However, the report further stated that tadpoles of frogs and metamorphosing salamanders would be killed with LC50 values of approximately 0.1 mg/L Noxfish. Sousa et al. (1988) also suggested that tadpoles and juvenile salamanders would probably be killed, but adult amphibians would not be seriously affected by rotenone applications.

With the exception of the data for adult frogs as presented by Farringer (1972), the 24-h LC50 of rotenone for various amphibians ranges from 0.1–0.580 mg/L (Table 1). Farringer (1972) reported much higher LC50 values (> 3.2 mg/L in all tests for Noxfish and Dri-Noxfish) than any other investigator, suggesting that adult frogs are considerably less sensitive to rotenone than amphibian larvae. Comparison of the 24-hour LC50 values for larval amphibians (Table 1) with those for fish (0.0165–0.665 mg/L for Noxfish, Marking and Bills 1976) strongly suggests the possibility that rotenone applications will result in considerable non-target amphibian mortality if an effective fish kill occurs.

Hamilton (1941) exposed tadpoles of *Rana pipiens* in various stages of metamorphosis to rotenone concentrations ranging from 0.01 to 0.5 mg/L. Tadpoles that had not begun metamorphosis exhibited the typical symptoms of suffocation by rising to the surface and gasping for air. Those tadpoles undergoing tail resorption basically remained at the surface of the rotenone solution to obtain air and exhibited sluggish muscular movements after several hours. Lethal concentration was 0.1 mg/L (Table 1), but time of death varied with the stage of metamorphosis. Tadpoles still undergoing gill respiration were killed within 8 h, while metamorphosed animals survived for 24 h. In a field study of the effects of Pro-Noxfish on nontarget organisms in ponds, substantial mortality of *R. pipiens* tadpoles was reported at a treatment of 5 µL/L (Burress 1982).

The response of metamorphosing salamanders (*Ambystoma tigrinum*) to rotenone was similar to that reported for tadpoles (Hamilton 1941). A lethal concentration of 0.1 mg/L for metamorphs was reported and concentrations as low as 0.0166 mg/L were toxic, but not necessarily fatal, for salamanders that had not resorbed their gills. Sublethal concentrations may be important causes of mortality since laboratory tests utilize death as an endpoint and do not monitor behavioral anomalies which may increase mortality in wild populations (Hall and Henry 1992). Apparently amphibian larvae with gills are most sensitive to rotenone.

Two other salamanders, *Amphiuma* and *Siren*, also may be susceptible to rotenone. Both of these large neotenic salamanders are obligately aquatic and inhabit freshwater ponds, ditches, streams, swamps, and lakes (Conant and Collins 1991). Effects of rotenone treatments on these salamanders may be pronounced due to their high rates of cutaneous respiration (Duellman and Trueb 1986) and their inability to leave the aquatic habitat.

At the 0.5 to 2 mg/L concentrations used in fisheries management, rotenone is reported to be nontoxic to mammals, birds, and reptiles (Sousa et al. 1987). However, no studies have been conducted to document the effects of rotenone treatment on reptiles. Carr (1952) stated that soft-shelled turtles (*Apalone* spp.) were susceptible to suffocation by concentrations of rotenone used in standard fisheries practices. Dundee and Rossman (1989) also suggested that softshell turtles are affected by rotenone. But authors of both books did not include discussion of potential rotenone toxicity for any other turtle species.

TABLE 1. Toxicity of rotenone to amphibians in laboratory tests.

Species	Stage	Temp °C	pH	Hardness (mg/L $CaCO_3$)	LC50 (mg/L) 24 h		LC50 (mg/L) 96 h		Formulation	Reference
Rana pipiens	juvenile/ adult	—	—	—	2.0?	[0.01]*	—		0.5% Rotenone in glycol	Haag 1931

*calculated values in brackets are standardized for % rotenone content and represent mg/L rotenone rather than mg/L of the formulation as reported in the literature.
**values in parentheses are 95% confidence intervals.
***LC50 at 48 h.
†Alkalinity.
††The 48- or 96-h LC50's were actually higher than this value which represented the highest concentration tested.

Because rotenone is a respiratory poison, tolerance generally varies inversely with oxygen requirements (Engstrom-Heg et al. 1978). Many aquatic turtles are capable of remaining submerged for long periods of time without pulmonary respiration due to specialized aquatic respiration mechanisms (Dunson 1960; Girgis 1961; Root 1949). Specifically, *Apalone spinifera* and *Kinosternon minor* utilize buccopharyngeal respiration (Belkin 1968; Dunson 1960) which involves pumping water in and out of the pharynx region where numerous villiform papillae of the buccal mucosa are highly vascularized (Girgis 1961). The skin and cloaca in turtles may also be modified for underwater respiration (Dunson 1960; Girgis 1961; Root 1949). Other turtles, including *Trachemys scripta* and *K. odoratum*, are capable of aquatic respiration, but to a lesser extent (Belkin 1968; Jackson and Schmidt-Nielsen 1966; Root 1949). Use of aquatic respiration (buccopharyngeal, skin, and/or cloacal) is likely the proximate cause for rotenone susceptibility in turtles. Although no published data exist documenting turtle mortality, their aquatic preference, in conjunction with delay in leaving the water once poisoning commences, may render them incapable of avoidance behavior. Species which are less dependent on aquatic respiration and leave the water upon treatment may be affected to a lesser degree.

Freshwater aquatic snakes do not utilize aquatic respiration and dermal absorption of rotenone is unlikely, but secondary poisoning by ingestion of affected fish or frogs is a possibility. Aquatic snakes such as water snakes (*Nerodia*), crayfish snakes (*Regina*), mud and rainbow snakes (*Farancia*), cottonmouths (*Agkistrodon piscivorus*), and the black swamp snake (*Seminatrix pygaea*) potentially would be most affected by rotenone applications. Haque (1971) reported mortality of one aquatic snake (no identification given) 48 h after rotenone treatment (1–2 ppm of Chem-Fish Special, 5% rotenone), but noted another snake swimming in the pond. Avoidance of the water by frogs also was reported. However, no conclusive evidence of the effects of rotenone on these animals was presented.

An additional consideration in evaluating non-target mortality following rotenone treatment is the proportion of animals surfacing and, therefore, becoming visible. Proportions of fish populations surfacing or remaining on the bottom varies with

species, water temperature, time, water depth, and presence of rooted aquatic plants (Bartoo 1977; Parker 1970). Amphibian larvae, aquatic turtles, and snakes may remain on the bottom of treated bodies of water, thereby concealing mortality.

Non-target mortality may be greatly reduced by certain management practices. Hockin et al. (1985) successfully managed rotenone treatment of fish compounds by providing several untreated areas as a refuge for small fish and larval stages of frogs, toads, and newts; access to untreated compounds was by passage through Netlon fence divisions. Additional protection for tadpoles abundant in one specific compound was provided by placement underwater along the fence division of a sheet of hessian sacking soaked in a saturated potassium permanganate solution. No mortality of non-target amphibians was reported.

The summary of a 1976 questionnaire sent to various states concerning the use of rotenone at concentrations above 1 ppm revealed that 83% of respondents (N = 174) noted no observed effect or effects unknown on non-target organisms, 4% reported some dead tadpoles, 1% reported some dead sirens, and <1% reported some dead salamanders. However, caution in interpretation of results was suggested, as the cause of death may not have necessarily been related to rotenone applications (Schnick 1977).

Review of the literature indicates that various factors may affect the toxicity of rotenone to amphibians and reptiles. Response to rotenone is species-specific, although animals utilizing a high degree of aquatic respiration are probably most susceptible. As shown for fish, tissue distribution and rates of uptake, detoxification and elimination are the apparent mechanisms responsible for differences in susceptibility to rotenone. In addition, exposure to various environmental contaminants (e.g., PCB's) may alter susceptibility to rotenone. Physical parameters affecting rotenone toxicity include temperature, pH, alkalinity, flow rate, turbidity, rotenone formulation, and dosage. Further, variable application rates, particularly those in excess of 2 ppm, may compromise the safety of non-target amphibians and reptiles. In light of these diverse environmental, physical and physiological factors which influence the toxicity of rotenone, additional investigations of effects on amphibians and reptiles are needed if these species are to be adequately protected in areas of rotenone use. The most urgent need is for additional acute toxicity testing for aquatic amphibian and reptile species, particularly aquatic turtles. Management of rotenone applications to lessen non-target mortality and adequate knowledge of the local distribution of amphibians and reptiles in treated habitats would greatly reduce the potential hazards to these aquatic animals.

ASIATIC HERPETOLOGICAL RESEARCH

Asiatic Herpetological Research is a new journal concerning, but not limited to, Asian herpetology. It is published by the Chinese Society for the Study of Amphibians and Reptiles, headquartered in Chengdu, China, and the Asiatic Herpetological Research Society at the Museum of Vertebrate Zoology, University of California, Berkeley.

THE EDITORS

The journal is edited by an internationally recognized group of experts on Asian amphibians and reptiles:

Editor: Ermi Zhao (China).

Managing Editors: J. Robert Macey and Theodore J. Papenfuss (both USA).

Editorial Board: Kraig Adler (USA), Natalia B. Ananjeva (Russia), Steven C. Anderson (USA), Aaron Bauer (USA), Leo Borkin (Russia), Bihui Chen (China), Ilya S. Darevsky (Russia), Indraneil Das (India), William E. Duellman (USA), Hajime Fukada (Japan), Carl Gans (USA), Huiqing Gu (China), Robert F. Inger (USA), Mahmoud Latifi (Iran), Kuangyang Lue (China), Ronald Marlow (USA), Robert W. Murphy (Canada), Göran Nilson (Sweden), Hidetoshi Ota (Japan), Jionghua Pan (China), Yunxu Tong (China), Keming Tu (China), Yuhua Yang (China), and Kentang Zhao (China).

THE JOURNAL

The format of the journal is 8.5 × 11 inches (21.5 × 28 cm). *All articles are in English.* There are many photographs, figures, and maps, plus occasional color plates. The following titles from recent issues are representative of journal coverage:

"Studies on Pakistan Reptiles," by Walter Auffenberg (USA) and Hafizur Rehman (Pakistan).

"Defensive Behavior and Feeding Biology of the Asian Mock Viper, *Psammodynastes pulverulentus*, a Specialized Predator on Scincid Lizards," by Harry W. Greene (USA).

"Reproduction of Chinese Alligators," by Zhengdong Zhang (China).

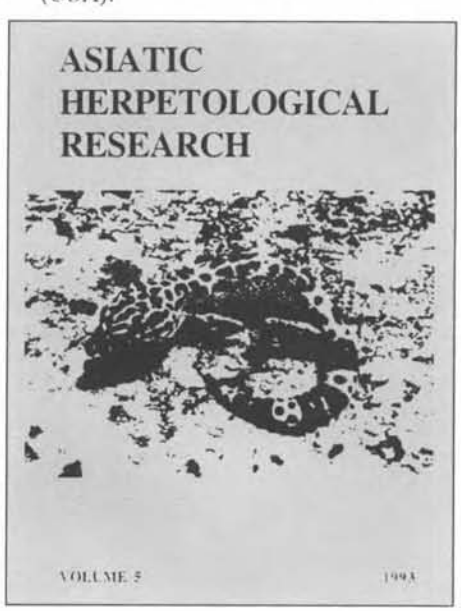
"The Reptile Fauna of the Kingdom of Bhutan with the Description of a New Species of Scincid Lizard," by Aaron M. Bauer (USA) and Rainer Günther (Germany).

"A New Species of the Genus *Paramesotriton* (Amphibia: Caudata) from Guangxi," by Yetang Wen (China).

"Species in the *Vipera kaznakowi* Complex in the Caucasus: Present Distribution, Possible Genesis, and Phylogeny," by Nikolai Orlov and Boris Tuniev (both Russia).

"The Type Locality of *Agkistrodon halys caraganus*," by Roger Conant (USA).

"Studies on Hynobiid Salamanders, With Description of a New Genus," by Kraig Adler (USA) and Ermi Zhao (China).



"Thermal Sensitivity of Sprinting and Clinging Performance in the Tokay Gecko (*Gekko gecko*)," by Jonathan B. Losos (USA).

"Holocene Anurans from the Caucasus," by Zbyněk Roček (Czech Republic).

"The Freshwater Turtle Trade in Bangladesh," by S. M. A. Rashid (Bangladesh) and Ian R. Swingland (UK).

"Reptiles of the Democratic People's Republic of Korea. Part I. Serpents," by Zbigniew Szyndlar (Poland) and Dam O. Hung (North Korea).

"Squamate Reptiles from Eastern Mindanao, Philippine Islands," by Brian E. Smith (USA).

"A New Species of *Varanus* from Yunnan, With Comparison Between It and Six Other Species from Southeast Asia," by Datong Yang and Simin Li (both China).

"Karyotypes of Some Species of *Bungarus*," by Michihisa Toriba (Japan).

"On the Ecology of Przewalsky's Gecko in the Transaltai Gobi, Mongolia," by Dimitri Semenov and Leo Borkin (both Russia).

"Intergradation Between *Melanochelys trijuga trijuga* and *M. t. coronata* (Testudines)," by Indraneil Das (India) and Peter C. H. Pritchard (USA).

"Mating Call Structure of the Chinese Frog, *Rana nigromaculata*," by Yong Mu and Ermi Zhao (both China).

"Studies on Early Embryonic Development of *Rana rugulosa* Wiegmann," by Jionghua Pan and Danyu Liang (both China).

MANUSCRIPTS

Manuscripts for publication are solicited and should be addressed to Asiatic Herpetological Research Society, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA (*fax*: 510–643–8238). Detailed instructions are published at the end of volume 5 (1993).

MEMBERSHIP AND SUBSCRIPTIONS

Individual memberships in the USA are US$25 per year; outside the USA $30. Library subscriptions in the USA are $45 per year; outside the USA $50. All members and subscribers receive one volume of *Asiatic Herpetological Research* per year. Address all membership or subscription correspondence to Asian Herpetological Research Society, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA. Back issues of volumes 2–5 (1988–1993) are available from the same address at the same price per volume. Volume 1 is out of print.

GRADUATE and POST-GRADUATE RESEARCH GRANTS

The Biological Research Station of the Edmund Niles Huyck Preserve offers grants (max. = $2500) to support biological research which utilizes the resources of the Preserve. Among the research areas supported are basic and applied ecology, animal behavior, systematics, evolution, and conservation. The 2000-acre Preserve is located on the Helderberg Plateau, 30 miles southwest of Albany. Habitats include northeast hardwood-hemlock forests, conifer plantations, old fields, permanent and intermittent streams, 10 and 100-acre lakes and several waterfalls. Facilities include a wet and dry lab, library, and houses/cabins for researchers. Deadline = February 1, 1995. Application material may be obtained from Dr. Richard L. Wyman, Executive Director, E.N. Huyck Preserve and Biological Research Station, P.O. Box 189, Rensselaerville, New York 12147.

Hemidactylus brooki (Gray) Lacks Abdominal Fat Bodies And Fat Pads

The presence of abdominal fat bodies is reported in a number of species of lizards from temperate and tropical parts of the world (Derickson 1976; Duvall et al. 1982; Fox 1977; Sarkar and Shivanandappa 1989). In temperate lizards, the fat bodies appear to serve as nutrient reserves during winter (Derickson 1976; Fox 1977). An inverse relation between fat body mass and gonadal cycles has been reported in some species of lizards from temperate as well as tropical regions. However, for a few species of tropical lizards, there is no clear relationship between the two (Derickson, 1976; Flemings 1993; Greenberg and Gist, 1985; Magnusson 1987; Vitt 1983). Among gekkonid lizards, Church (1962) reported the absence of fat bodies in three Javanese species, *Cosymbotus platyurus*, *Hemidactylus frenatus*, and *Peropus mutilatus*. The Mediterranean gecko, *Hemidactylus turcicus*, possesses a single, small, triangular-shaped fat body extending forward from the anterior margin of the pelvic girdle (Selcer 1992). Furthermore, it has additional lipid storage sites in the form of discrete subcutaneous fat pads extending from the axilla to the hindlimbs, being more prominent posteriorly.

In this communication, we report the absence of abdominal fat bodies and subcutaneous fat pads in the south Indian gekkonid, *Hemidactylus brooki*. This species inhabits human dwellings and is a multi-clutched, monoautochronic lizard having an extended breeding season from November to June. About 25–35 lizards were collected every month from October 1992 to September 1993. A total of 350 adult lizards (151 males, 199 females), collected in Dharwad city (15°17′N, 75°3′E), were dissected and examined. Snout-vent lengths of these lizards ranged from 40 mm (minimum size at sexual maturity) to 65 mm.

Church (1962) attributed the absence of fat bodies in the three gekkonid species he studied to relatively uniform climatic conditions and constant food supply; therefore, perhaps these species are continuous breeders. On the other hand, in *H. turcicus*, a multi-clutched seasonal breeder, the fat deposits are depleted completely in females during production of the first clutch and are not replenished until after reproduction has ceased. Similar observations are made in other genera of seasonally breeding multi-clutched lizards (Etheridge et al. 1986; Hahn and Tinkle 1965; Shanbhag and Prasad 1992). Food availability is considered to be an ultimate factor determining whether or not lipids are stored (Derickson 1976). The adaptive value of stored lipids in most lizards is that reproduction may occur during periods of unpredictable or fluctuating resource availability. The situation in *H. brooki* is unlike that of other gekkonid species studied thus far. For instance, although it is a seasonal breeder it does not store lipids in the form of fat bodies or fat pads. Presumably, this reflects the presence of a relatively constant food supply.

Acknowledgment.—This work was partly supported by Grant No. F.3. 17/94 (SAP-II) of UGC, New Delhi, under the Special Assistance Programme.

POINTS OF VIEW

Human Nature And Peer Review: An Argument For Anonymity

I read with interest Wilson and McCranie's (1993) critique of the anonymous peer review system. Clearly, their experience with the peer review system is considerable, given their extensive publication histories and editorial experience. I have reviewed six manuscripts for three herpetology journals and one general science journal and have published seven peer-reviewed articles during the six years I have been actively engaged in research. Although admittedly less experienced than Wilson and McCranie, I hope my views will bring the perspective of a less established researcher into the discussion on the merits of anonymity.

After acknowledging that peer review is a necessary component of the publication process, Wilson and McCranie outlined several pros and cons of anonymity in the peer review system. They cite several herpetological editors who favor preservation of the anonymous system and outline the pro-anonymity arguments as follows:

1. The anonymous system protects less established persons against retribution by established colleagues.
2. Anonymity encourages free expression.
3. Anonymity levels the "playing field" by forcing authors to thoughtfully consider the comments of a reviewer without knowledge of reviewer's status.

Ultimately, Wilson and McCranie dismiss these arguments, and suggest the anonymous peer review system should be replaced with an onymous system because:

1. The anonymous system is cumbersome and time consuming.
2. Vindictive reviewers are sheltered.
3. Science should be conducted openly and to behave otherwise amounts to academic dishonesty.
4. Anonymity provides a vehicle for persons seeking to keep others from publishing competing results.
5. The anonymous system is a form of cowardice.
6. The anonymous system discourages a cooperative atmosphere.

The arguments outlined above, both pro and con, undoubtedly have some basis in truth. Each of us can probably recall a conversation during which someone claimed their work was enhanced or unfairly assaulted within the framework of the anonymous review system. Some of us have even been exposed to individuals boasting about how they used the anonymous system to exact retribution.

All systems are prone to abuses, and Wilson and McCranie are right to point out the need for periodic evaluation of the status quo. They have diligently outlined several problems with anonymous review and, at a minimum, their critique reiterates the need to be ever watchful for abuses in the system. However, I believe their critique underestimates the effect onymity would have on the objective nature of our field.

In a recent commentary on Wilson and McCranie's suggestions, Pisani (1994) wrote that editors and scientists are "human first and scientists/editors second." Pisani's point illustrates the inherent conflict that we all face between subjective human nature and the objective nature of science. It has been my experience that anonymity dulls subjectivity and enhances objectivity. For example, I am personally acquainted with four of the six authors whose papers I peer reviewed. During the reviews, I made every effort to divorce our personal relationship from my evaluation of their work. Knowing that I would remain anonymous to the authors greatly enhanced my ability to approach objectivity (consciously and presumably subconsciously). In an onymous system, I believe it would been immeasurably more difficult to detach the relationships I had with the authors from my evaluation of their work.

As a reviewee, only one of the 20+ peer reviews I have received was signed. The review was positive and, like it or not, I feel beholden to that individual. Given the small number of people involved in most scientific specialties (e.g., snake physiology, turtle nesting) and the probability that persons familiar with the subject matter will act as reviewers, onymous peer review appears likely to favor human nature over the objective nature of science.

Wilson and McCranie limit their discussion to the effects of anonymous peer review on the scientific community. However, most scientists have patrons (e.g., granting agencies, private foundations, industry, taxpayers) and research results often impact those patrons. Because our results don't only impact us, it is important that persons outside our community have confidence in the integrity of our system of checks and balances. For example, I recently published a dietary analysis of sea turtles in New York waters (Burke et al. 1993). The results of my analysis will presumably be the basis for decisions regarding habitat protection in New York. The publication of my study following rigorous peer review by persons unknown to me can only strengthen its credibility and therefore its value to my patron, the New York State Department of Environmental Conservation.

To summarize, anonymous peer review was primarily set up to insure that research results are critiqued as objectively as possible. An offshoot of this system is patron and public confidence in the integrity of the field employing anonymous peer review. It is my opinion that these two points counterbalance and perhaps outweigh the objections to anonymity raised by Wilson and McCranie.

Acknowledgments.—I thank S. Patterson, K. Buhlmann, and J. W. Gibbons, each of whom represents varying degrees of experience with the peer review system, for their comments on the manuscript. Manuscript preparation was aided by contract DE-AC09-76SROO819 between the U.S. Department of Energy and the Savannah River Ecology Laboratory.

SNAKE INSPECTORS NEEDED

Work in your area as a Herpetologist/Snake Inspector for on-call, part-time position. Must have flexible hours, be readily contactable, have own transportation, conservative appearance, and 5–10 years experience working with snakes. Must be at least 25 years old, know local snakes and any laws governing their protection. Positions available in the following states: VA, WV, NC, SC, GA, FL, AL, MD, MS, AR, LA, TN, TX, NM, AZ, CA. Send resumé no later than 1 February 1995 to: *Mr. Weeks, 1913 Dannemora Drive, Virginia Beach, Virginia 23456.*

HERPETOLOGICAL HUSBANDRY

Stimulation Of Ingestion In Solenoglyphous Snakes

Many studies have shown that various vipers and pitvipers prefer envenomated over nonenvenomated rodents in experimentally arranged choice situations (Burghardt 1970; Chiszar et al. 1983; Duvall et al. 1980). Recent projects have indicated that this effect depends upon puncture wounds inflicted by snake fangs and an action of venom on rodent internal tissues and not upon the extemal presence of venom and snake saliva on the prey's hair (Chiszar et al. 1992; Lavin-Murcio et al. 1993). Based on this accumulation of data, it was hypothesized at Rio Grande Zoo (RGZ) that poor-feeding solenoglyphs might be induced to ingest rodent carcasses that have been envenomated by conspecifics who are not reluctant to strike or swallow. The hypothesis was tested first with a captive-born, 13-month old urutu *(Bothrops alternatus)* that had accepted *Mus musculus* five times in four weeks after birth, but then refused all food for the next 12 months. An adult conspecific envenomated a mouse, which was then placed into the juvenile's cage. The prey was ingested during the night, and this experiment was successfully repeated one and two weeks later. The same approach was taken with a juvenile ocellate mountain viper (*Vipera wagneri*) that had a poor feeding history during five months at the zoo. This animal ingested a conspecifically envenomated mouse within 3 h and this experiment was successfully repeated one week later.

At the University of Colorado, the same attempt was made with four poor-feeding adult prairie rattlesnakes (*Crotalus v. viridis*), and all accepted conspecifically envenomated mice within 2–12 h. Two of these snakes had never fed in captivity (six months) and two ate sporadically (no more than six times per year with prey being offered every 14 days, a schedule on which two dozen other *C. v. viridis* accept prey at almost every opportunity). Three of the four snakes ate conspecifically envenomated mice again 14 days after the first such feeding; the fourth snake refused the second prey.

At the University of Northern Colorado, conspecifically envenomated *M. musculus* were offered to two western diamondback rattlesnakes (*Crotalus atrox*). One was an adult that had refused food (wild and domestic, live and dead *M. musculus*) consistently for 15 months, and the other was a juvenile that had refused prey four times over six months. Both ingested conspecifically envenomated mice within 2 h. Two poor-feeding banded rock rattlesnakes (*Crotalus lepidus klauberi*) also accepted conspecifically envenomated prey within 4 h. For the juvenile *C. atrox* and both *C. l. klauberi*, the same mice which had been refused for 12 h were accepted after being envenomated by conspecifics. Finally, two adult dusky pigmy rattlesnakes (*Sistrurus miliarius barbouri*) were poor feeders, never having accepted prey since their arrival in Colorado five months prior. Since no good-feeding conspecifics were available to envenomate prey, venom was expressed from the *S. m. barbouri* and 10 microliters of crude venom was injected into each of two mice (4.3 g each), which were then placed into the cages of the respective snakes. One of these *S. m. barbouri* ate within 10 h, the other did not.

It is noteworthy that the urutu at RGZ and the adult western diamondback at University of Northern Colorado have subsequently begun to strike and ingest untreated *M. musculus*. The urutu, after accepting untreated mice twice, again refused. The same mouse was offered the next day after being envenomated by a conspecific, and the snake then ingested the mouse. This has happened four times.

Several hypotheses could be adduced to explain the willingness of poor feeders to take conspecifically envenomated prey (e.g., Chiszar et al. 1992; Thomas and Pough 1979). For the present, however, we intend only to recommend this RGZ effect as a husbandry strategy for solenoglyphous snakes that refuse to feed in captivity. It would be of interest to determine whether poor-feeding elapid snakes will also accept envenomated prey. Finally, we encourage researchers to study the use of reconstituted lyophilized venom in stimulating ingestion, as this might provide a useful and safe procedure in cases where conspecific snakes are unavailable to envenomate prey for poor-feeding singletons.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in volume 25, number 1.

CAUDATA

AMBYSTOMA TIGRINUM (Tiger Salamander). USA: GEORGIA: Chattahoochee Co: ca. 200 m W of Box Springs Road and 5.2 km N of Shamanski Road. (89°39'08"N, 32°28'05"W). 17 February 1994. John B. Jensen. Verified by Craig Guyer. Auburn University (AUM 33684). Many egg masses and larvae observed; several larvae collected and preserved. New county record.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1416 Cape Lane, Niceville, Florida 32578, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: GEORGIA: Floyd Co: Stretch Road, Berry College campus, 1.77 km WNW jct. Rt. 27 and main entrance to college (34°17'44"N, 85°12'01"W). 15 February 1992. S. L. DeFauw and P. J. English. Verified by Gerald K. Williamson and Robert A. Moulis. Savannah Science Museum (SSM 12551). Adult DOR; new county record. Martof (1956, Amphibians and Reptiles of Georgia, Univ. Georgia Press, Athens. 94 pp.) surmised a patchy distribution throughout the state.

Submitted by **SHERRI L. DEFAUW**, McPherson College, McPherson, Kansas 67460, USA, and **PATRICK J. ENGLISH**, 306 Oak Park Drive, McPherson, Kansas 67460, USA.

ANURA

BUFO MICROSCAPHUS MICROSCAPHUS (Arizona Toad). USA: ARIZONA: Coconino Co: Clear Creek at Hamilton Crossing, SW1/4, SW1/4 Sec. 29, T15N, R13E. 26 June 1994. S. DeMarais. Photo on file at Arizona Game and Fish Department, Nongame Branch Fisheries Program (Photo DBD001). Verified by Brian K. Sullivan, Arizona State University. Extends the known range 10 km NE from East Clear Creek at Mack's Crossing (Sullivan 1993, Great Basin Nat. 53:402–406), indicating that this species may occur significantly farther downstream in Clear Creek north of the Mogollon Rim.

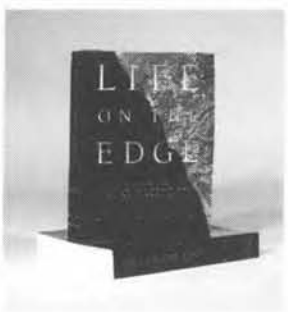
Submitted by **SCOTT DeMARAIS** and **DANA WATERS**, Arizona Game and Fish Department, Nongame Brance, 2221 West Greenway Road, Phoenix, Arizona 85023, USA.

BUFO WOODHOUSII WOODHOUSII (Woodhouse's Toad). USA: TEXAS: Sherman Co: Coldwater Creek crossing (N side) at Farm Road 119, ca. 22.5 km S jct. with U.S. Rt. 54 (36°16'15"N, 101°49'23"W), 1059 m elev. 19 May 1994. J. D. Johnson and T. J. LaDuc. Verified by R. G. Webb. University of Texas at El Paso (UTEP 15652–53). First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998-0500 and Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **TRAVIS J. LaDUC**, Laboratory for Environmental Biology, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

CENTROLENE ANDINUM (NCN). VENEZUELA: ZULIA: Distrito Perijá, Serranía de Perijá, Trayecto de La Escalera a La Cascada, 1400 m elev. Colección de Vertebrados de la Universidad de Los Andes, Mérida (CVULA IV-3933, adult female); and a juvenile (CVULA IV-3934) referred to this species from Sierra de Perijá, Campamento El Desastre, 2050 m. Nancy Sierra. Verified by John D. Lynch. New state records; these discoveries significantly extend the species range ca. 210 air km NW from the type locality, making this the northernmost record for this frog. CVULA VI-3934 is also a maximum elevation record for the species, previously known only from elevations between 840–1050 m in the Mérida Andes (La Marca 1992, Cuadernos Geográficos 9:19).

Submitted by **ENRIQUE LA MARCA**, Instituto de Geografia y Conservación de Recursos Naturales, Universidad de Los Andes, Apartado 116, Mérida 5101-A, Venezuela.



ELEUTHERODACTYLUS PERUVIANUS (NCN). BOLIVIA: SANTA CRUZ: Amboró National Park (18°40'S, 63°35'W). 21 December 1988 and 22 September 1990. Paolo Bettella and Nelson Vaca. Verified by William E. Duellman. MNK (Museo Noel Kempff, Santa Cruz de la Sierra, Bolivia) 189, 191, 236, 358–61, 365, 374. First record for the country. Most literature reports of *Eleutherodactylus fenestratus* from this region may actually correspond to *E. peruvianus* (De la Riva 1990, Boll. Mus. reg. Sci. nat. Torino 8:261–319; De la Riva 1993, Rev. Esp. Herpetol. 7:97–105). Most common species of the genus in the area. Advertisement calls have been also heard in two localities in the Departamento Cochabamba: Bulo-Bulo (17°16'S, 64°20'W) and Valle de Sajta (17°00'S, 64°50'W). These records extend the distribution about 800 km southeastward (air line) from the closest known locality in Pampas del Heath, Madre de Dios, Peru (12°35'S, 68°40'W) (Icochea 1993, Mem. X Cong. Nac. Biol., Perú, pp. 351–354). Bolivian populations lack the yellow or orange spots on the posterior surface of thighs characteristic of Peruvian and Ecuadorian specimens.

Submitted by **IGNACIO DE LA RIVA**, Natural History Museum, The University of Kansas, Lawrence, Kansas 66045-2454, USA.

ELEUTHERODACTYLUS PLANIROSTRIS PLANIROSTRIS (Greenhouse Frog). USA: LOUISIANA: Plaquemines Parish: 4.0 km NE Belle Chasse on Tulane University Herbert Center grounds. 2 September 1994. Harold A. Dundee. Verified by Robert A. Thomas. TU 23352. This specimen, a spotted phase phenotype, was captured on the loading platform of the building housing Tulane University's Museum of Natural History Herpetological Collection. On 3 October 1994, while moving some rotting wooden boxes that had been stored on the loading plaform, six additional spotted specimens were captured and several others escaped. These latter captures are now TU 23358-23363. How the species arrived there is unknown; no horticultural plants are located on the entire 500 acre plot of the Hebert Center, which is mostly heavily forested or grassed, but other developments about 2 km distant do have horticultural plantings. All specimens captured or seen are essentially adult size, but although plenty of prey items are constantly seen on the platform, I cannot visualize that a clutch of eggs could have been laid and successfully survived atop bare cement, even though covered by a box; variation in size suggests several different arrival times. The species is now widely distributed in the nearby city of New Orleans and its suburbs on the opposite side of the Mississippi River; these latter records are the first from west of the Mississippi River. A colony at my home, started with a few individuals in 1982 but not being seen again until about 1988, became very abundant in 1991 when rainfall in the area was more than double the usual ca. 63 inches, then waned to where I saw only a couple per year in 1992 and 1993. But late in 1994 they have been appearing in modest numbers despite a very dry year until late summer. I strongly suspect that the species will turn up in many communities along the Gulf Coast via importation with horticultural plants from Florida nurseries, but the agility of these frogs can enable them to spread rapidly once established.

LIFE ON THE EDGE

A Guide to California's Endangered Natural Resources: Wildlife

"California has long awaited and sorely needed this compilation of images and ideas, punctuated with mythology and supported by accurate and readable science."

Dr. John E. McCosker, Director, Steinhart Aquarium, California Academy of Sciences

One of the most beautiful and comprehensive natural history books ever produced, *Life on the Edge* describes 115 of California's threatened and endangered wildlife species, with detailed discussions of conservation and recovery. Meticulously researched, essential to the professional, rewarding to the general reader, this volume is a visual and intellectual delight!

- Over 500 full-color pages
- Lively essays and interviews with such resource experts as R. Stebbins, R. Dasmann and K. Norris
- Extensive historical sections
- Foreword by Peter H. Raven, Director of the Missouri Botanical Garden

Hardcover: $75.00 Paperback: $39.50

Available in bookstores or call BioSystems Books at 1-800-983-5433 (*Life*)

Submitted by **HAROLD A. DUNDEE**, Tulane University Museum of Natural History, Belle Chasse, Louisiana 70037-3098, USA.

EPIPEDOBATES PETERSI (NCN). BRAZIL: ACRE: Jurua River, left bank, municipality of Cruzeiro do Sul, Sobral (72°49'W, 8°22'S). 9 March 1992. Claude Gascon. Verified by James P. Bogart. Instituto Nacional de Pesquisas da Amazônia (INPA 4407–09, 4429, 4437, 4491, 4525, 4557, 4615, 4631, 4637, 4687, 4731, 4738–39, 4776–77, 4779–80). First record for Brazil. This species was known only from a few localities in the Amazon drainage of Peru (Rodriguez and Myers 1993, American Mus. Novitates 3068:1–15).

Submitted by **CLAUDE GASCON**, Ecologia/INPA, CP 478, 69011-970 Manaus, Amazonas, Brazil.

HYLA CINEREA (Green Treefrog). USA: ALABAMA: Calhoun County: small pond near Jacksonville, 4.8 km S of junction of Ala. Rt. 204 and Ala. Rt. 21, and ca. 1.6 km E of Ala. Rt. 21, Sec. 35, T14S, R8E. 28 June 1994. E. Sowhren, M. Boudreaux, P. Rodgers. Jacksonville State University Collection (JSUC A001). Verified by G. R. Cline. New county record; fills gap in distribution, suggesting a bridge between the sporadic populations occurring in the Appalachian Plateau and the Ridge and Valley provinces (Mount 1975, The Reptiles and Amphibians of Alabama. Auburn Univ. Exp. Sta., Alabama. 347 pp.; Conant and Collins 1991, Field Guide to Reptiles and Amphibians of Eastern and Central North America, Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). This suggests that the species may also be found in these provinces in northwestern Georgia.

Submitted by **ERIC C. SOEHREN**, **MELISSA C. BOUDREAUX**, and **C. PAUL ROGERS**, Department of Biology, Jacksonville State University, Jacksonville, Alabama 36265, USA.

HYLA FEMORALIS (Pine Woods Treefrog). USA: LOUISIANA: East Baton Rouge Par: Lee Price Road, 2.5 km W of La. Rt. 37, Baywood. 11 July 1994. J. Boundy and S. Shively. LSUMZ 56721–56722. East Feliciana Par: La. Rt. 959, 2.5 km W of LA 63. 11 July 1994. J. Boundy and S. Shively. LSUMZ 56726. All verified by David A. Good. Extend range ca. 25 km W of locality in SE St. Helena Parish (Dundee and Rossman 1989, Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge. 300 pp.). All were males calling in young pine plantations.

Submitted by **JEFF BOUNDY**, Museum of Natural Science, Louisiana State University, Baton Rouge, Louisiana 70803, USA, and **STEVE SHIVELY**, Natural Heritage Program, Louisiana Department of Wildlife & Fisheries, P. O. Box 98000, Baton Rouge, Louisiana 70898, USA.

HYLA GRATIOSA (Barking Treefrog). USA: GEORGIA: Floyd Co: Stretch Road, Berry College campus, 2.08 km WNW jct. Rt. 27 and main entrance to college (34°18'01"N, 85°12'12"W). 2 May 1993. S. L. DeFauw and A. A. Kinsey. Verified by Gerald K. Williamson and Robert A. Moulis. Savannah Science Museum (SSM 12554). DOR adult. New county record; extends the range ca. 74.7 km NE of nearest known locality in Calhoun County, Alabama (Mount 1975, The Reptiles and Amphibians of Alabama. Auburn Univ. Exp. Sta., Alabama. 347 pp.). Martof (1956, Amphibians and Reptiles of Georgia, Univ. Georgia Press, Athens. 94 pp.) noted occurrences in the Cumberland Plateau.

Submitted by **SHERRI L. DEFAUW**, McPherson College, McPherson, Kansas 67460, USA, and **ANDREW A. KINSEY**, Department of Biology, Berry College, Mount Berry Station, Georgia 30149, USA.

HYLA PLATYDACTYLA (NCN). VENEZUELA: ZULIA: Distrito Perijá, Serranía de Perijá, Campamento El Temor, 1825m elev. Nancy Sierra. Verified by John D. Lynch. Colección de Vertebrados de la Universidad de Los Andes, Mérida, CVULA IV-3936. First state record (La Marca 1987, 37a. Conv. Anual AsoVAC, noviembre

1987:267; La Marca 1987, Herpetol. Rev. 18(3):57; Viloria y Calchi 1993, Biollania 9:37–69); represents the northernmost locality for the species and extends known range ca. 240 air km NW of closest known locality in the Mérida Andes and ca. 260 air km N of nearest record in the state of Táchira.

Submitted by **ENRIQUE LA MARCA**, Instituto de Geografia y Conservación de Recursos Naturales, Universidad de Los Andes, Apartado 116, Mérida 5101-A, Venezuela.

PHYLLOBATES LUGUBRIS (Dart-Poison Frog). PANAMA: PROVINCIA DE PANAMA: Distrito de Capira, Cirí Grande (8°57'18"N, 80°03'38"W), 160–180m elev. 12 February 1993. C. A. Jaramillo, M. Arrunátegui, Q. Fuenmayor, F. Sánchez. Verified by A. Stanley Rand. Círculo Herpetológico de Panamá (CH-3904). Previous known localities for this species in Panamá were within the Provincia de Bocas del Toro (Savage 1968, Copeia 1968:745–776). Myers and Daly (1983, Sci. Amer. 248(2):120–133) extended this range eastward by presenting an approximate distribution of *P. lugubris* on a map; however, they did not provide information on specific localities. New province record; extends range of this species further east, outside the area shown by Myers and Daly (1983).

Submitted by **ROBERTO IBAÑEZ D.**, Smithsonian Tropical Research Institute, Apartado 2072, Balboa, Republica de Panamá, **CESAR A. JARAMILLO**, Círculo Herpetológico de Panamá, Apartado 10762, Estafeta Universitaria, Panamá, Republica de Panamá, and **FRANK A. SOLIS**, Departamento de Zoología, Escuela de Biología, Universidad de Panamá, Republica de Panamá.

PHYLLOPEZUS POLLICARIS PRZEWALSKYI (Ututo Macho). ARGENTINA: SALTA: Departamento de Anta, Ranch Campo Grande (24°36'S, 63°18'W), 85 km N and 12 km E from J. V. Gonzalez. 1–4 February 1993. E. O. Lavilla, G. J. Scrocchi and F. B. Cruz. Verified by G. J. Scrocchi. Instituto de Herpetologia, Fundación Miguel Lillo (EL 1370-FML-S 03027, EL 1475-FML-S 03041, EL 1491/92-FML-S 03042). First province record; cited before in Argentina from Misiones, Corrientes, Chaco and Santiago del Estero (Cei 1993, Mus. Reg. di Scienze Nat. Torino. Monog. XIV. 949 pp.)

Submitted by **FÉLIX B. CRUZ, GUSTAVO J. SCROCCHI**, and **ESTEBAN O. LAVILLA**, Instituto de Herpetologia, Fundación Miguel Lillo, Miguel Lillo 251, (4000) Tucuman, Argentina.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: ILLINOIS: Shelby Co: 5 km S Towerhill and 3 km W Towerhill/Herrick blacktop road (39°20'44"N, 88°59'48"W). 20 March 1994. Allan Wilson. Southern Illinois University Department of Zoology Collection (SIUC H-4636). Montgomery Co: 1.4 km W Middle Fork Shoal Creek bridge on Rt. 16 and 1.2 km S (39°9'33"N, 89°30'54"W). 6 March 1994. Chris Schmedeke and Allan Wilson. Both verified by Ronald A. Brandon. SIUC H-4587–88. New county records (Smith 1961, Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **ALLAN K. WILSON**, Rural Route 2, Box 147, Ramsey, Illinois 62080, USA.

PSEUDACRIS OCULARIS (Little Grass Frog). USA: FLORIDA: Okaloosa Co: Niceville, roadside ditch along Bayshore Drive ca. 0.5 km west of Palm Boulevard, SW 1/4 Sec. 17, T1S, R22W. 13 July 1994. J. B. Jensen. Verified by Paul Moler. Florida Museum of Natural History (UF 91658). New county record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 3, The Amphibians. Windward Publ., Miami). Extends known range ca. 15 km W (Moler 1982, Herpetol. Rev. 13:131).

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1416 Cape Lane, Niceville, Florida 32578, USA.

PSEUDACRIS TRISERIATA TRISERIATA (Western Chorus Frog). USA: ILLINOIS: Montgomery Co: 1.4 km W Middle Fork Shoal Creek bridge on Rt. 16 and 1.2 km S (39°9'33"N, 89°30'54"W). 6 March 1994. Chris Schmedeke and Allan Wilson. Verified by Ronald A. Brandon. Southern Illinois University Department of Zoology Collection (SIUC H-4589 and H-4590). New county record (Smith 1961, Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **ALLAN K. WILSON**, Rural Route 2, Box 147, Ramsey, Illinois 62080, USA.

RANA CAPITO SEVOSA (Dusky Gopher Frog). USA: FLORIDA: Walton Co: SE 1/4 SE 1/4 Sec. 4, T2N, R21W. 23 February 1994. John B. Jensen. Verified by Paul E. Moler. UF Photograph 89755. One adult male found AOR. New county record. Frog apparently heading to a nearby pond in which the author previously discovered 57 Dusky Gopher Frog egg masses on 14 February 1994. Individual was photographed and released due to threatened status in state. Five additional breeding ponds have since been located in the county.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, P. O. Box 1150, Niceville, Florida, 32588-1150, USA.

RANA CATESBEIANA (Bullfrog). USA: COLORADO: El Paso Co: pond at W end of golf course, Air Force Academy, 9.6 K N Colorado Springs. 17 June 1994. David O. Norris, Edmund J. Clark, and Tucker Kellogg. Verified by Hobart M. Smith. UCM 56889. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife. 131 pp.); westernmost range in Colorado E of the divide. Second straight year of sightings; metamorphosing tadpoles captured with seine net at perimeter of pond.

Submitted by **DAVID O. NORRIS, EDMUND J. CLARK**, and **TUCKER KELLOGG**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

1994 Herpetological Index

Compiled by Breck Bartholomew & Dr. P. Zwart

- Index to over 3,000 papers published primarily during 1994
- Complete bibliography to:
  - √ *Alytes (V. 1-12)*
  - √ *Proceedings of the Desert Tortoise Council Symposium (1976-1992)*
  - √ *Chinese Herpetological Research/Asiatic Herpetological Research (V. 1-5)*
- Many of the *Smithsonian Herpetological Information Service* Publications
- Index to more than 2,000 papers on Herpetological diseases & pathology
- Available in three formats $15 ea. or $20 for two:
  - Booklet
  - Macintosh disk (EndNote & text files)
  - DOS disk (EndNote & text files)

Send orders to:
Breck Bartholomew

Logan, UT 84321-3905, USA

SCAPHIOPUS HOLBROOKII HOLBROOKII (Eastern Spadefoot). USA: GEORGIA: Floyd Co: Berry College main campus, 0.8 km WNW jct. Rt. 27 and main entrance to college (34°17'32"N, 85°11'24"W). 21 August 1992. S. L. DeFauw and P. J. English. Verified by Gerald K. Williamson and Robert A. Moulis. Savannah Science Museum (SSM 12552–53). Both specimens were collected from a temporary pastureland pool following a hard rain (8.9 cm accumulation in a 12 hour period). New county record; verifies presumed distribution in the Ridge and Valley physiographic province of northwestern Georgia (Martof 1956, Amphibians and Reptiles of Georgia. Univ. Georgia Press, Athens. 94 pp.).

Submitted by **SHERRI L. DEFAUW**, McPherson College, McPherson, Kansas 67460, USA,, and **PATRICK J. ENGLISH**, 306 Oak Park Drive, McPherson, Kansas 67469, USA.

SCHARTHYLA OSTINODACTYLA (NCN). BRAZIL: AMAZONAS: Jurua River, right bank, municipality of Eirunepé, Sacado, (70°51'W, 6°46'S). 16 September 1991. Claude Gascon. Verified by James P. Bogart. Instituto Nacional de Pesquisas da Amazônia (INPA 2572, 2637, 2641, 2652, 2800, 2844–5, 2848, 2884–6). First record for Brazil; species was only known from a few localities in Peru (Duellman and Sá 1988, Trop. Zool. 1:117–136). Other localities in Amazonas where this species was collected are: Jurua River, left bank, municipality of Eirunepé, Condor (70°51'W, 6°45'S), 14 September 1991, (INPA 2549); Jurua River, right bank, municipality of Eirunepé, Penedo, (70°45'W, 6°50'S), 22 August 1991, (INPA 2321, 2347–48, 2354–6, 2402, 2408); Jurua River, left bank, municipality of Eirunepé, Nova Empreza, (70°44'W, 6°48'S), 24 August 1991, (INPA 2340, 2370, 2434, 2504); Jurua River, left bank, municipality of Itamarati, Barro Vermelho, (68°46'W, 6°28'S), 28 October 1991, (INPA 3386); Jurua River, right bank, municipality of Itamarati, Jainu, (68°46'W, 6°29'S), 17 October 1991, (INPA 3080, 3160, 3162, 3212–15, 3226, 3238–39, 3439, 3444, 3452, 3481); Jurua River, left bank, municipality of Itamarati, Altammira (68°54'W, 6°35'S), 22 November 1991, (INPA 5212); Jurua River, left bank, municipality of Jurua, Vira-Volta, (66°14'W, 3°17'S), 5 June 1992, (INPA 5752); in Acre: Jurua River, right bank, municipality of Cruzeiro do Sul, Nova Vida, (72°49'W, 8°22'S), 17 March 1992, (INPA 4653, 4667, 4675, 4721, 4753, 4755).

Submitted by **CLAUDE GASCON**, Ecologia/INPA, CP 478, 69011-970 Manaus, Amazonas, Brazil.

TESTUDINES

APALONE SPINIFERA (Spiny Softshell). USA: COLORADO: Denver Co: 15 m S recently drained Garland Park pond and 100 m N of Cherry Creek. 12 June 1994. R. M. Engeman. Verified by Richard E. Mauldin. Live adult (carapace length 33 cm). Denver Wildlife Research Center Archives color slide accession 94/3. New county record; nearest record is ca. 30 km N on South Platte River in Weld County (Hammerson 1982, Amphibians and Reptiles in Colorado, Colorado Div. Wildlife. 131 pp.), of which Cherry Creek is a tributary.

Submitted by **RICHARD M. ENGEMAN**, Denver Wildlife Research Center, P. O. Box 25266, Bldg. 16, Denver Federal Center, Denver, Colorado 80225-0266, USA.

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: NEBRASKA: Cheyenne Co: Buffalo Bend. 22 May 1994. David and Adam Chiszar, Richard L. Holland, Carolyn Ristau, and H. M. Smith. Verified by Lauren Livo. UCM Color Slides 80–81. First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA; **RICHARD L. HOLLAND**, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA; **CAROLYN RISTAU** and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

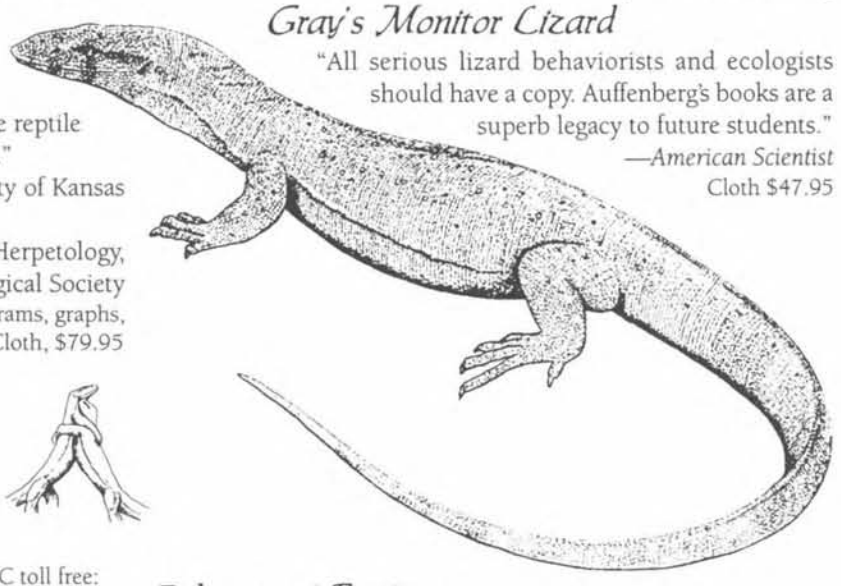
CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: NEBRASKA: Kimball Co: Lodgepole Creek, 1.6 km

The Bengal Monitor

New from Walter Auffenberg

"The most thorough and exhaustive study of a single reptile species ever carried out. . . . It will become a classic."
—Henry Fitch, University of Kansas

"An unparalleled accomplishment in herpetology."
—John L. Behler, curator, Department of Herpetology, New York Zoological Society



588 pp. 4 b&w photographs, 151 figures (including diagrams, graphs, and maps), 100 tables, appendixes, bibliography, index. Cloth, $79.95

—also by Walter Auffenberg

Gray's Monitor Lizard

"All serious lizard behaviorists and ecologists should have a copy. Auffenberg's books are a superb legacy to future students."
—*American Scientist*
Cloth $47.95

Behavioral Ecology of the Komodo Monitor

"A landmark book."—*Bulletin of the Chicago Herpetological Society*
Cloth $59.95

UNIVERSITY PRESS OF FLORIDA

GAINESVILLE, TALLAHASSEE, TAMPA, BOCA RATON, PENSACOLA, ORLANDO, MIAMI, JACKSONVILLE

N Kimball. 16 July 1993. Brian R. Roh. Verified by John D. Lynch. University of Nebraska State Museum (UNSM 15112). New county record from the extreme southwestern panhandle of Nebraska (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **BRIAN R. ROH**, Department of Biology, University of Nebraska, Lincoln, Nebraska 68588-0118, USA.

CHRYSEMYS PICTA BELLII (Western Painted Turtle). USA: COLORADO: Phillips Co: Settling Ponds, 1.6 km E Haxtun. 11 July 1994. Richard L. Holland and H. M. Smith. Verified by Lauren Livo. UCM 56891 and Laboratorio de Biogeografia, Universidad de Los Andes, Mérida, Venezuela (ULABC 3907). First county record (Hammerson 1986, Amphibians and Reptiles in Colorado, Colorado Division of Wildlife. 131 pp.).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA; **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA; **CAROLYN RISTAU** and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

CHRYSEMYS PICTA BELLII (Western Painted Turtle). USA: NEBRASKA: Cheyenne Co: Buffalo Bend. 22 May 1994. Richard L. Holland, David and Adam Chiszar, Carolyn Ristau, and H. M. Smith. Verified by Lauren Livo. UCM Color Slides 82–83. First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA; **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA; **CAROLYN RISTAU** and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

MACROCLEMYS TEMMINCKII (Alligator Snapping Turtle). USA: MISSISSIPPI: Sharkey Co: Big Sunflower River at Red Rock Boat Ramp, Delta National Forest, Rt. 16, 20.8 road km SE of Rolling Fork, Sec. 12, T12N, R6W. 19 October 1993. K. J. Killgore, et al. Northeast Louisiana University Color Slide 70483; Big Sunflower River, 3.2 river km S of Rt. 14 Bridge, Sec. 23, T13N, R6W. 27 October 1993. S. G. George, et al. NLU Color Slide 70484; Sunflower Co: Quiver River, 1.3 river km N of Hannah's bridge, Sec. 33, T22N, R3W. 6 October 1993. J. J. Hoover and S. L. Harrel. NLU Color Slide 70485; Big Sunflower River at Rt. 49W bridge, 3.2 road km S of Indianola, Sec. 8, T19N, R5W. 5 December 1993. S. G. George and J. J. Hoover. NLU Color Slide 70486. All specimens were verified by Neil H. Douglas and represent new county records.

Submitted by **STEVEN G. GEORGE, JAN JEFFERY HOOVER**, and **K. JACK KILLGORE**, U.S. Army Engineer Waterways Experiment Station, ER-A, 3909 Halls Ferry Road, Vicksburg, Mississippi 39180-6199, USA.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). USA: COLORADO: Sedgwick Co: Road 15, 2 mi S Road 14. 12 July 1994. Richard L. Holland. Verified by David Chiszar. UCM Color Slides 84–85. First county record and northernmost record in state (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife. 131 pp.).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

LACERTILIA

AMEIVA AUBERI OBSOLETA (Exuma Islands Ameiva). BAHAMAS: GREAT BAHAMA BANK: Exuma Islands, Exuma Cays Land and Sea Park, Shroud Cay. July 1993. R. Franz, C. K. Dodd, Jr. Verified by David L. Auth. UF 89622. New island record (Franz et al. 1993, Caribbean Journ. Sci. 29[3–4]:165–173).

AMPHIBIANS AND REPTILES NATIVE TO MINNESOTA

Barney Oldfield and John J. Moriarty
Foreword by W. J. Breckenridge

The only guide to amphibians and reptiles of the Upper Midwest, this valuable reference includes 116 color photographs and 49 maps. Its distribution maps, keys, and natural history data will prove invaluable to the natural resource manager, field biologist, and amateur herpetologist.

$25.95 cloth/jacketed 256 pages 7 3/8″ x 10 1/2″

Barney Oldfield, a veterinarian, and **John J. Moriarty**, a wildlife specialist for Hennepin Parks in Minnesota, have combined 25 years of experience studying and observing Minnesota's amphibians and reptiles. Together and independently, they have conducted numerous herpetological projects within Minnesota, including herpetofauna surveys of the southwest and southeast regions, county surveys, and field research projects on individual species.

MINNESOTA

Submitted by **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, and **C. KENNETH DODD, JR.**, National Biological Survey, 412 N. E. 16th Avenue, Room 250, Gainesville, Florida 32601, USA.

ANOLIS CAROLINENSIS (Green Anole). USA: LOUISIANA: West Carrol Parish: residence on Gould Street, Lake Providence, 4 December 1993. C. Toney and G. Toney. Verified by Neil H. Douglas. Northeast Louisiana University Museum of Zoology (NLU 70478). New parish record; fills gap in the northeastern portion of the state. (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **STEVEN G. GEORGE**, U. S. Army Engineer Waterways Experiment Station, ER-A, 3909 Halls Ferry Rd. Vicksburg, Mississippi 39180-6199, USA.

ANOLIS SAGREI ORDINATUS (Bahamian Brown Anole). BAHAMAS: GREAT BAHAMA BANK: Exuma Islands, Exuma Cays Land and Sea Park, Elbow Cay. UF 89611; Hawksbill No. 1 (island between Hawksbill and Little Hawksbill cays). UF 89618; Little Cistern Cay. UF 89612; O'Briens Cay. UF 89620–21. All July 1993. R. Franz, C. K. Dodd, Jr. All verified by David L. Auth. New island records (Franz et al. 1993, Caribbean Journ. Sci. 29[3–4]:165–173).

Submitted by **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, and **C. KENNETH DODD, JR.**, National Biological Survey, 412 N. E. 16th Avenue, Room 250, Gainesville, Florida 32601, USA.

BASILISCUS BASILISCUS BARBOURI (NCN). VENEZUELA: ESTADO MERIDA: Distrito Campo Elías, Ejido, La Quebrada, sector Saladito, inmediaciones del Instituto Universitario Tecnológico de Ejido, 1200m elev. 13 September 1993. Tulio Enrique Salazar Ruíz. Verified by Pascual J. Soriano M. Colección de Anfibios y Reptiles, Núcleo de Biogeiografía de Montaña, Instituto de Geografia y Conservación de Recursos Naturales de la Universidad de Los Andes (ULABG 3426). The subspecies was first reported for the Venezuelan Andes, without indication of museum numbers, from "Estado Mérida: Río Chama," and "Estado Táchira: Palmira, Rio Tarbes (Torbes?)," by Donoso-Barros (1968, Carib. Journ. Sci. 8: 113). ULABG voucher specimen is the first documented record for the Venezuelan Andes, extending the range ca. 400 km SE of the type locality. It is a female bearing pale throat markings that differ from those exhibited by Sierra de Perijá female specimens reported by La Marca [1987, Herpetol. Rev. 18(3):57; 1987, 37a. Conv. Anual AsoVAC, noviembre 1987:267] as *Basiliscus basiliscus* by Donoso-Barros (1968, Carib. Journ. Sci. 8:113) or as *Basiliscus basiliscus barbouri* by Viloria and Calchi (1993, Biollania 9:42). Throat markings should be investigated as a potential diagnostic character for the subspecies, since most keys, like those of Peters and Donoso-Barros (1970, U.S.Natl. Mus. Bull. 297) and Gorzula (1978, Serie Boletín Técnico M. A. R. N. R., DG 11 A/BT/01/78), rely solely on male crest differences.

Submitted by **ENRIQUE LA MARCA**, Instituto de Geografia y Conservación de Recursos Naturales, Universidad de Los Andes, Apartado 116, Mérida 5101-A, Venezuela, and **JUAN JOSÉ GARCÍA MILANO**, Laboratorio de Invertebrados de Los Andes, Urbanización Humboldt, Bloque 5, Edificio 02, Apartamento 0102, Mérida 5101, Venezuela.

CYRTOPODION KOTSCHYI (Kotschy's Gecko). GREECE: MUNICIPALITY (NOMOS) OF ETOLIAS-AKARNANIAS: Province (Eparchia) of Navpaktias, 5 km S Platanos (38°35'N, 21°48'E), ca. 600 m elev. 1 May 1994. H. Bringsøe. Verified by W. Böhme. Zoologisches Forschungsinstitut und Museum Alexander Koenig, Bonn (ZFMK 57501). In mainland Greece north of the Peloponnese, *C. kotschyi* is known to have a coastal distribution, whereas it is more widespread on the peninsula of the Peloponnese [Beutler 1981, pp. 53–74 *In* Böhme (ed.), Handbuch der Reptilien und Amphibien Europas, Band 1, Echsen 1, Akad. Verlagsges., Wiesbaden; Bringsøe 1985, Ann. Musei Goulandris 7:271–318]. This record fills a gap in the hitherto known limit of distribution towards the Greek inland north of the Gulf of Corinth and is situated between the recorded localities of Agrinion and Amphissa as illustrated by Beutler (1981, *op. cit.*).

Submitted by **HENRIK BRINGSØE**, Esthersvej 7, DK-4600 Køge, Denmark.

EUMECES OBSOLETUS (Great Plains Skink). USA: COLORADO: Sedgwick Co: S side Platte River, 30 m E Rt. 59. 12 July 1994. Richard L. Holland and Hobart M. Smith. Verified by David Chiszar. UCM 56898. First county record and northernmost record in state (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife. 131 pp.).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

GERRHONOTUS INFERNALIS (Texas Alligator Lizard). MEXICO: HIDALGO: municipality of Meztitlán, Rancho Shalteno, about 2.5 km SW Zoquizoquipan (20°38'N, 98°43'W), 1980 m elev. 13 October 1984. Fernando Mendoza Quijano and Roberto Zapata Morales. Verified by Oscar Flores-Villela. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de Mexico (UNAM MZFC-4875). First record for the state of Hidalgo and a range extension southeastward of ca. 260 airline km from records reported by Good (1994, Herpetol. Monogr. 8:180–202) in San Luis Potosí (at Alvarez and in the Alvarez Mts. at Km. 42 on the Potosí-Río Verde Railroad). Although it generally has been considered a subspecies of *G. liocephalus*, Good (1994) demonstrated the species status of *G. infernalis*. Good found no evidence that *G. infernalis* and *G. ophiurus* (another former subspecies of *G. liocephalus*) are sympatric, but *G. ophiurus* occurs at El Chilaco, Hidalgo (1260 m elev.), 10 km NW of Rancho Shalteno. Hence the two species may be sympatric or parapatric, or there may be an enclave of *G. infernalis* within the range of *G. ophiurus*.

Submitted by **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de Mexico, A.P. 70-399, Distrito Federal 04510, México, and **DAVID A. GOOD**, Museum of Natural Science, 119 Foster Hall, Louisiana State University, Baton Rouge, Louisiana 70803, USA.

HEMIDACTYLUS GARNOTII (Indo-Pacific Gecko). BAHAMAS: LITTLE BAHAMA BANK: Abaco, Man O' War Cay. August 1992. Nancy Albury. Verified by David L. Auth. UF 87191–94. First record for the Bahamas (introduced) (Schwartz and Henderson 1991, Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville. 720 pp.).

Submitted by **SANDRA D. BUCKNER**, P. O. Box N-8893, Nassau, Bahamas, and **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA.

HEMIDACTYLUS MABOUIA (Tropical House Gecko). BAHAMAS: GREAT BAHAMAS BANK: New Providence Island, Nassau, at Retirement Road. 23 September 1992. UF 87202; Nassau, at Buen Retiro. 7 December 1992. UF 87201, 87204; Nassau, at Ludens on Dowdeswell Street. 23 December 1992. UF 87203, 87205. D. Knowles, S. D. Buckner. All verified by David L. Auth. Second record for the Bahamas; first record for New Providence (Franz et al. 1993, Caribbean Journ. Sci. 29[3–4]:165–173).

Submitted by **SANDRA D. BUCKNER**, P. O. Box N-8893, Nassau, Bahamas, and **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA.

TURTLES OF THE UNITED STATES AND CANADA

Carl H. Ernst, Jeffrey E. Lovich, and Roger W. Barbour

"This will be a major contribution as a reference book for wildlife biologists and naturalists."—J. Whitfield Gibbons, University of Georgia

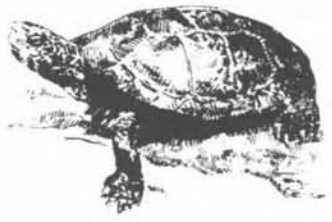
The first comprehensive update in twenty years, this book provides a survey of the 56 turtle species in the United States and Canada, with color plates and black-and-white photographs of each species, anatomical line drawings, and distribution maps.

57 color, 241 b&w photographs, 63 line illus.
682 pp. Cloth: 1-56098-346-9H $60.00

THE REPTILES OF VIRGINIA

Joseph C. Mitchell
Foreword by Roger Conant

"The first complete catalogue of the reptiles of Virginia, from the sea turtles of the Atlantic coast to the snakes, turtles, and lizards of the piedmont and Blue Ridge Mountains. . . . The book yields a wealth of new information on the ecology, life histories, and biogeography of reptiles in the state. . . . An informative tool for amateur and professional herpetologists, naturalists, and science teachers."—*Virginia Wildlife*



"The results chronicled here are of encyclopedic depth."—Roger Conant, University of New Mexico

63 color, 4 b&w illus., 7 line illus., 62 maps 384 pp.
Cloth: 1-56098-356-6H $40.00

TURTLES OF THE WORLD

Carl H. Ernst and Roger W. Barbour

"The first [book] to provide comprehensive coverage of the world's 257 turtle species. . . . Each species is covered under the headings of description, distribution, habitat and natural history. . . . An impressive piece of scholarship."—*Nature*

50 color, 143 b&w illus., 5 tables, 21 line drawings
290 pp. Paper: 1-56098-212-8P $24.95

VENOMOUS REPTILES OF NORTH AMERICA

Carl H. Ernst • American Library Association Outstanding Reference Source

"In-depth information is provided for [21] species concerning habitat, reproduction, growth and longevity, venom, feeding behavior, and more."—*Science Teacher*

55 color, 61 b&w illus. 248 pp. Cloth: 1-56098-114-8H $35.00

HEMIDACTYLUS MABOUIA (Tropical House Gecko): USA: FLORIDA: Glades Co: Palmdale, Palmdale Campgrounds. 3 June 1994. W. E. Meshaka, Jr. Verified by R. D. Bartlett. USNM 244446. Adult male collected on building at night. Other exotic species were observed (*Anolis sagrei*) or collected (*H. garnotii*, *Osteopilus septentrionalis*). New county record detects inland colony disjunct from and probably transported from extreme southern Florida where it is widespread (Lawson et al. 1991, Herpetol. Rev. 22:11–12; Butterfield et al. 1993, Herpetol. Rev. 24:111–112; Meshaka et al. 1994, Herpetol. Rev. 25:80–81).

Submitted by **WALTER E. MESHAKA, JR.**, Archbold Biological Station, P. O. Box 2957, Lake Placid, Florida 33852, USA, **BRIAN P. BUTTERFIELD** and **J. BRIAN HAUGE**, Department of Zoology and Wildlife Sciences, 331 Funchess Hall, Auburn University, Auburn, Alabama 26489-5414, USA.

LEIOCEPHALUS CARINATUS VIRESCENS (Exuma Islands Curlytail Lizard). BAHAMAS: GREAT BAHAMA BANK: Exuma Islands, Exuma Cays Land and Sea Park, Shroud Cay. July 1993. R. Franz, C. K. Dodd, Jr. Verified by David L. Auth. UF 89622. New island record (Franz et al. 1993, Caribbean Journ. Sci. 29[3–4]:165–173).

Submitted by **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, and **C. KENNETH DODD, JR.**, National Biological Survey, 412 N. E. 16th Avenue, Room 250, Gainesville, Florida 32601, USA.

OPHISAURUS ATTENUATUS LONGICAUDUS (Eastern Slender Glass Lizard). USA: FLORIDA: Baker Co: 21 km E Lake City (30°14'N, 82°23'W). 27 April 1989. K. M. Enge. Verified by David L. Auth. UF 72750. New county record representing first peninsular record N of Alachua County (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians. Windward Publ., Miami. 191 pp.). Captured by drift fencing in longleaf pine flatwoods at Olustee Battlefield State Historic Site.

Submitted by **KEVIN M. ENGE**, Florida Game and Fresh Water Fish Commission, Route 7, Box 3055, Quincy, Florida 32351, USA.

OPHISAURUS COMPRESSUS (Island Glass Lizard). USA: FLORIDA: Baker Co: 21 km E Lake City (30°14'N, 82°23'W). 24 April 1989. K. M. Enge. Verified by David L. Auth. UF 72749. New county record; partially fills hiatus between Columbia County and the Atlantic Coast (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles and Crocodilians. Windward Publ., Miami. 191 pp.). Captured by drift fencing in longleaf pine flatwoods at Olustee Battlefield State Historic Site.

Submitted by **KEVIN M. ENGE**, Florida Game and Fresh Water Fish Commission, Route 7, Box 3055, Quincy, Florida 32351, USA.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). USA: FLORIDA: Escambia Co: Sabine Drive, 0.3 km–1.3 km N and NE of Fort Pickens Road, Santa Rosa Island, T3S, R29W. 30 May 1993 and 8 May 1994. John B. Jensen and Jodie B. Bell. Verified by Craig Guyer. Auburn University, Alabama (30 May 1993, AUM 33692; 8 May 1994, AUM 33693, 33694, 33695). New county record. One individual was collected DOR 30 May 1993. Subsequently, three additional specimens, also DOR, were collected 8 May 1994. This introduced species apparently has a well established population in the vicinity of the given location.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1416 Cape Lane, Niceville, Florida, 32578, USA.

PRISTIDACTYLUS ACHALENSIS (Pampa de Achala Copper Lizard). ARGENTINA: CORDOBA: Department Rio Cuarto, 19 km NW Alpa Corral (32°2'S, 64°42'W) on rocky place on summit ("pampa de altura") of Sierra de Comechingones (Cerro de Oro

site). 28 February 1994. Luciano Javier Avila. Verified by Ricardo A. Martori. Herpetological collection of Zoologia de Vertebrados, Departamento de Cienceas Naturales, Universidad Nacional de Rio Cuarto, Argentina [ZV-UNRC 2977 (male) and 2976 (female)]. Extends range ca. 100 km from population on Cerro Champaquí, Department Calamuchita. (Cei 1986, Mon. IV, Mus. Reg. Sci. Nat. Turín. 527 pp.).

Submitted by **LUCIANO JAVIER AVILA**, Departamento de Ciencias Naturales, Universidad Nacional de Rio Cuarto, Est. Post. Nro. 9, C. P. 5800, Rio Cuarto (Córdoba), Argentina

SPHAERODACTYLUS NIGROPUNCTATUS GIBBUS (Exuma Islands Black-spotted Ground Gecko). BAHAMAS: GREAT BAHAMA BANK: Exuma Islands, Exuma Cays Land and Sea Park, Little Cistern Cay (UF 89616), Little Hawksbill Cay (UF 89617), Shroud Cay (UF 89623). July 1993. F. Franz, C. K. Dodd, Jr. All verified by David L. Auth. New island records (Franz et al. 1993, Caribbean Journ. Sci. 29[3–4]:165–173).

Submitted by **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida, 32611, USA, and **C. KENNETH DODD, JR.**, National Biological Survey, 412 N. E. 16th Avenue, Room 250, Gainesville, Florida 32601, USA.

SPHAERODACTYLUS NOTATUS AMAURUS (Great Bahama Bank Reef Gecko). BAHAMAS: GREAT BAHAMA BANK: Exuma Islands, Exuma Cays Land and Sea Park, Little Cistern Cay. UF 89614–15; O'Briens Cay. UF 89626; Shroud Cay. UF 89624. All July 1993. R. Franz, C. K. Dodd, Jr. All verified by David L. Auth. New island records (Franz et al. 1993, Caribbean Journ. Sci. 29[3–4]:165–173).

Submitted by **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, and **C. KENNETH DODD, JR.**, National Biological Survey, 412 N. E. 16th Avenue, Room 250, Gainesville, Florida 32601, USA.

SERPENTES

BOTHROPS MOOJENI (Brazilian Lancehead). BRAZIL: MATO GROSSO: 2 km N Porto Jofre on Rodovia Transpantaneira. 16 September 1993. Wolfgang Wüster and Stephen Pierini. Verified by Miguel Trefaut Rodrigues. Instituto Butantan (IB 55112). First record from inside Pantanal, ca. 120 km S of nearest record from Poconé (Campbell and Lamar 1989, Venomous Reptiles of Latin America. Comstock, Ithaca, New York. 425 pp.). This confirms these authors' prediction of its presence within the Pantanal. The specimen was found dead on the road in a zone of permanently dry higher ground with cerrado vegetation. The species is probably absent from the floodplain that constitutes most of the Pantanal. Fieldwork funded by European Community.

Submitted by **WOLFGANG WÜSTER**, Department of Zoology, University of Aberdeen, Tillydrone Avenue, Aberdeen AB9 2TN, Scotland, United Kingdom, **STEPHEN PIERINI**, 93 Putnoe Lane, Bedford, MK41 9AH, England, United Kingdom, and **GIUSEPPE PUORTO**, Laboratório de Herpetologia, Instituto Butantan, Avenida Vital Brasil 1500, CEP 05503-900 São Paulo—SP, Brazil.

[Editor's note: The above record originally appeared, with printing errors, in Herpetol. Rev. 25(2):76. It is reprinted here in its entirety.]

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer). USA: NEBRASKA: Hitchcock Co: 0.8 km E 23.3 km S Culbertson. 23 July 1993. Brian R. Roh. Verified by John D. Lynch. University of Nebraska State Museum (UNSM 15124). County record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **BRIAN R. ROH**, Department of Biology, University of Nebraska, Lincoln, Nebraska 68588-0118, USA.

CROTALUS ADAMANTEUS (Eastern Diamondback Rattlesnake). USA: SOUTH CAROLINA: Allendale Co: E side of Rt. 3, 4.95 km S jct. S.C. Rt. 301. 13 December 1989. Jess Way. Verified from photos by James L. Knight. South Carolina State Museum (SCSM Photo 94.33). Gibbons and Semlitsch (1991, Guide to the Reptiles and Amphibians of the Savannah River Site. Univ. Georgia Press, Athens. 131 pp.) note that *C. adamanteus* has not been reported within 80 km of the southern border of the Savannah River Site (SRS). This specimen extends the range of this snake to within ca. 12 air km of the SRS southern boundary and is believed to be the first report of this species in Allendale County.

Submitted by **CHUCK SMITH**, 4942 Platt Springs Road, Box 7, West Columbia, South Carolina 2916, USA.

CROTALUS HORRIDUS (Timber Rattlesnake). USA: FLORIDA: Walton Co: DOR S side Lake Jackson marsh, SW 1/4 Sec. 27, T6N, R21W. 9 July 1994. J. B. Jensen, B. W. Mansell and P. E. Moler. Verified by David Auth. Florida Museum of Natural History (UF 91594). County record and first Florida record west of Apalachicola River (Allen 1949, Copeia 1949:73–74; Ashton and Ashton 1981, Handbook of Reptiles and Amphibians of Florida. Part 1, The Snakes. Windward Publ., Miami, Florida. 176 pp.). Species has been observed in Covington County, Alabama, ca. 36 km NW of this site (Jensen, pers. observ.) and represents the closest previously known locality.

Submitted by **JOHN B. JENSEN**, Florida Natural Areas Inventory, 1416 Cape Lane, Niceville, Florida 32578, USA; **BARRY W. MANSELL**, 2826 Rosselle Street, Jacksonville, Florida 32205, USA; and **PAUL E. MOLER**, Florida Game and Fresh Water Fish Commission, 4005 South Main Street, Gainesville, Florida 32601, USA.

DIADOPHIS PUNCTATUS ARNYI (Prairie Ringneck Snake). USA: TEXAS: Sherman Co: Coldwater Creek crossing (N side) at Farm Road 119, ca. 22.5 km S jct. with U.S. Rt. 54 (36°16'15"N, 101°49'23"W), 1059 m elev. 19 May 1994. J. D. Johnson and T. J. LaDuc. Verified by R. G. Webb. University of Texas at El Paso (UTEP 15640). First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998-0500 and Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

ELAPHE GUTTATA (Corn Snake). BAHAMAS: LITTLE BAHAMA BANK: Grand Bahama Island, (two adults) specific data unknown (specimens at the Bahamian Dept. of Agriculture); (juvenile) 2.6 mi east of Eight-Mile Rock at "The Fishing Hole." 22 June 1993. R. Neck. Verified by David L. Auth. UF 89403. First records for the Bahamas; introduced (Schwartz and Henderson 1991, Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville. 720 pp.).

Submitted by **SANDRA D. BUCKNER**, P. O. Box N-8893, Nassau, Bahama, and **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA.

ELAPHE OBSOLETA (Rat Snake). BAHAMAS: LITTLE BAHAMA BANK: Abacos, Marsh Harbour, government dock. November 1992. Simeon Pinder. Verified by David L. Auth. UF 87206 (small juvenile). First record for the Bahamas; introduced (Schwartz and Henderson 1991, Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville. 720 pp.).

Submitted by **SANDRA D. BUCKNER**, P. O. Box N-8893, Nassau, Bahama, and **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA.

LAMPROPELTIS TRIANGULUM (Milk Snake). USA: WYOMING: Campbell Co: Sec 1, R71W, T49N, 4 km S of Wyodak (Wyodak is located 8.5 km E of Gillette). 28 September 1992. Rusty Bird. Presented to Gordon W. Schuett. Verified by Fred Kraus. UMMZ 203656. A female neonate (SVL = 23.2 cm; TL = 4.2 cm; mass = 7.2 g) found moving on the ground surface in rocky terrain near habitat consisting of grass and sage brush at 1825 h. Died several days after capture. New county record; first documented specimen from northeast Wyoming (Baxter and Stone 1980, Amphibians and Reptiles of Wyoming. 2nd ed. Wyoming Game and Fish Department, Cheyenne. 137 pp.; Williams 1988, Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*. 2nd ed. Milwaukee Pub. Mus., Wisconsin. 176 pp.; C. J. McCoy, pers. comm.). Albany Co: SR 34, 54.4 km E of Bosler and 1.02 km E of the Sybille Canyon Research and Visitor Center. 6 May 1992. Paul Buttenhoff. Presented to Gordon W. Schuett. Verified by Fred Kraus. UMMZ 203657. Adult female found AOR at 1036 h at air temperature of 25–27°C, sky overcast with light rain. Died in captivity. New county record (see above references). These two records bring to 11 the documented specimens of *L. triangulum* from Wyoming.

Submitted by **GORDON W. SCHUETT**, Department of Life Sciences, Arizona State University West, P. O. Box 37100, Phoenix, Arizona 85069-7100, USA.

Breeding Reptiles & Amphibians

A collection of papers selected from the
BRITISH HERPETOLOGICAL SOCIETY BULLETIN
1980-1992
Edited by
SIMON TOWNSON
Published by
The British Herpetological Society
c/o The Zoological Society of London, Regent's Park, London NW1 4RY
© British Herpetological Society 1994 ISBN 0 9507371 51

Species and subjects covered include:-

LIZARDS *Lacerta strigata - Lacerta armeniaca - Podarcis lilfordi - Lacerta schreiberi - Lacerta vivipara - Lacerta agilis - Anguis fragilis - Agama stellio - Sauromalus obesus - Uromastyx acanthinurus - Shinisaurus crocodilurus - Tiliqua nigrolutea - Gerrhonotus multicarinatus - Basiliscus plumifrons - Chameleo johnstoni - Bradypodion thamnobates*; **SNAKES** *Pituophis melanoleucus - Elaphe rufodorsata - Rhabdophis tigrinus - Lampropeltis triangulum sinaloae - Gonyosoma oxycephala - Elaphe mandarina - Natrix natrix - Chondropython viridis - Lichanura trivirgata - Epicrates cenchria cenchria - Bitis nasicornis - Vipera ursinii*; **CROCODILES, ALLIGATORS, TORTOISES AND TURTLES** *Testudo marginata - Crocodylus porosus - Alligator mississipiensis - Chelonia mydas* - Politics of Conservation - Turtle Farming and Ranching; **NEWTS, SALAMANDERS, TOADS AND FROGS** Garden Ponds - *Notophthalmus viridescens - Triturus vulgaris - Triturus karelini - Triturus cristatus - Euproctus asper - Bufo calamita - Bufo viridis - Pelobates fuscus insubricus - Bombina - Rana esculenta - Pelodytes punctatus - Gastrotheca marsupiata - Eleutherodactylus johnstonei - Hyperolius marmoratus.*

262 Pages containing 20 colour plates and 50 black and white plates.

	Worldwide surface mail	£3.06	❑
	Worldwide airmail	£6.50	❑

International money orders & cheques should be made payable to: **British Herpetologial Society.**

Orders should be sent to: The Secretary, British Herpetological Society, c/o Zoological Society of London, Regent's Park, London NW1 4RY U.K.

LEPTOTYPHLOPS HUMILIS (Western Blind Snake). USA: ARIZONA: Coconino Co: Little Colorado River (LCR) Gorge: River Mile 5, S side of the river. 6 May 1991. J. A. Cole. Verified by Charles J. Cole. AMNH 139734. Record suggests that this species occurs reasonably continuously from the LCR corridor to the Mainstem Colorado River and continues along the Colorado River to its known historical range. Has not been identified to subspecies.

Submitted by **JEFFREY A. COLE**, Navajo Department of Fish & Wildlife, P. O. Box 1480, Window Rock, Arizona 86515, USA.

NERODIA SIPEDON SIPEDON (Northern Water Snake). USA: COLORADO: Logan Co: Dune State Wildlife Area. 21 May 1994. Richard L. Holland. Verified by Lauren Livo. UCM 56887. First county record; northeasternmost record in state (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife. 131 pp.).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA; **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA; and **CAROLYN RISTAU** and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

PITUOPHIS MELANOLEUCUS (Gopher Snake). USA: WASHINGTON: Skamania Co: adjacent to Columbia River, 0.2 km SW of Spring Creek National Fish Hatchery, NE 1/4 Sec. 28, T3N, R10E. 3 June 1994. W. P. Leonard and E. Phenix. Verified by Greg Schneider. UMMZ 206415. New county record; extends range ca. 18 km W along N side of Columbia River (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. of Idaho Press, Moscow. 332 pp.)

Submitted by **WILLIAM P. LEONARD**, Washington Department of Natural Resources—Natural Heritage Program, P. O. Box 47046 Olympia, Washington 98504-7046, USA, and **ERIK PHENIX**, 2800 Limited Lane, Apt. Q3, Olympia, Washington 98502, USA.

REGINA SEPTEMVITTATA (Queen Snake). USA: SOUTH CAROLINA: Barnwell Co: Tinker Creek at Rt. 161 bridge, 1.9 km W jct. Rts. 161 and 125 (9.0 km NE Williston). 17 May 1994. Rudolf G. Arndt and students. Verified by Alvin L. Braswell. North Carolina State Museum of Natural Sciences (NCSM 37136). New county record; extends range ca. 70 km E of the nearest shown edge of its range on the Edgefield-Aiken County boundary (Thompson 1982, A Guide to the Amphibians, Reptiles and Mammals of South Carolina. Privately published, Columbia. 134 pp.), which agrees with Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed., Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). This snake gave birth to nine young on 15 August 1994 (NCSM 37137–145).

Submitted by **RUDOLF G. ARNDT**, Faculty of Natural Sciences and Mathematics, The Richard Stockton College of New Jersey, Pomona, New Jersey 08240, USA.

RHADINAEA FLAVILATA (Pine Woods Snake). USA: FLORIDA: Gulf Co: N Port St. Joe, 1.5 km E U.S. Rt. 98 on S side County Road 382, Sec. 36, T7S, R11W. 26 February 1992. K. M. Enge. Verified by David L. Auth. UF 91091. First record for county and fourth record from the Florida panhandle W of Jefferson County (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 1. The Snakes. Windward Publ., Miami, Florida. 176 pp.; Palis 1992, Herpetol. Rev. 23:92; Irwin 1993, Herpetol. Rev. 24:110). Male discovered under trash in disturbed mesic flatwoods.

Submitted by **KEVIN M. ENGE**, Florida Game and Freshwater Fish Commission, Route 7, Box 3055, Quincy, Florida 32351, USA.

SONORA SEMIANNULATA (Ground Snake). USA: TEXAS: Sherman Co: Coldwater Creek crossing (N side) at Farm Road 119, ca. 22.5 km S jct. with U.S. Rt. 54 (36°16'15"N, 101°49'23"W), 1059 m elev. 19 May 1994. J. D. Johnson and T. J. LaDuc. Verified by R. G. Webb. University of Texas at El Paso (UTEP 15642). First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station. 434 pp.).

Submitted by **TRAVIS J. LaDUC**, Laboratory for Environmental Biology, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998-0500 and Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

TANTILLA NIGRICEPS (Plains Blackhead Snake). USA: COLORADO: Crowley Co: J Road, 4.9 km E Rt. 71. 18 June 1994. David Chiszar. Verified by Richard L. Holland. UCM 56890. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife. 131 pp.).

Submitted by **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

TANTILLA NIGRICEPS (Plains Blackhead Snake). USA: TEXAS: Sherman Co: Coldwater Creek crossing (N side) at Farm Road 119, ca. 22.5 km S jct. with U.S. Rt. 54 (36°16'15"N, 101°49'23"W), 1059 m. 19 May 1994. T. J. LaDuc and J. D. Johnson. Verified by R. G. Webb. University of Texas at El Paso (UTEP 15639). First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station, Texas. 434 pp.).

Submitted by **TRAVIS J. LaDUC**, Laboratory for Environmental Biology, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998-0500 and Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA.

THAMNOPHIS RADIX (Plains Garter Snake). USA: ILLINOIS: Jersey Co: NW1/4 Sec. 20, T6N, R11W, Ill. Rt. 100 at Elsah Road. 16 May 1994. J. Tucker. Verified by C. Phillips. Illinois Natural History Survey (INHS 11262). Adult DOR. County record; extends documented range 100.8 km S of Scott County record and 52.6 km WNW of isolated record for Madison County (Smith 1961, Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 1005 Edwardsville Road, Wood River, Illinois 62095, USA.

VIRGINIA VALERIAE (Smooth Earth Snake). USA: TENNESSEE: Wilson Co: Cedars of Lebanon State Forest, in woods adjacent Cedar Forest Road, ca. 3 km N Simmons Bluff Road jct. 21 April 1990. B. T. Miller, M. Donovan, D. Donovan. Middle Tennessee State University (MTSU 27S, 28S, 29S). Cannon Co: pasture off Sinks-Miller Road, ca. 1 km W Burt-Burgen Road. B. T. Miller, J. L. Miller. MTSU 85S. Verified by Robert Powell. New county records; extend the known distribution into the eastern rim of the width of the suspected hiatus separating *V. v. valeriae* and *V. v. elegans*. (Powell et al. 1992, Cat. Amer. Amph. Rept. 552.1–552.6).

Submitted by **BRIAN T. MILLER** and **JOYCE L. MILLER**. Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). ***HR*** especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints.

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Techniques, Natural History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles or Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes, and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of external reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

RWH

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc., 1388 N. 1293 Rd, Lawrence, Kansas 66046. *Herpetological Review* is composed using Microsoft Word and Aldus PageMaker on Apple Macintosh computers. Camera-ready copy is produced on a Linotronic 230 Imagesetter at Valley Type & Design, Fresno, California. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

Catalogue Of American Amphibians And Reptiles

The Catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 580	$290.00
INDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages	$5.00
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$6.00
IMPRINTED POST BINDER: (*Note:* one binder holds about 200 accounts)	$35.00
INCOMPLETE SET: NUMBERS 1 - 190	$75.00
191 - 410	$85.00
411 - 580	$130.00

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology.*** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1994

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*

Institutional subscription.....$60.00

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

About the Cover.—The cover illustrations were executed by Jeffrey W. Tamplin, Department of Zoology & Physiology, Louisiana State University, Baton Rouge. Clockwise, from upper left: *Thamnophis exsul* (USNM 166423, holotype: Coahuila); *Thamnophis sumichrasti* (USNM 7079a: Veracruz); *Thamnophis scalaris* (MVZ 144489: Veracruz); *Thamnophis mendax* (LSUMZ 35340: Tamaulipas). Readers interested in the systematics of this group of Mexican garter snakes are referred to the following publication: D. A. Rossman. 1992. Taxonomic status and relationships of the Tamaulipan montane garter snake, *Thamnophis mendax* Walker, 1955. Proc. Louisiana Acad. Sci. 55:1–14.

SSAR BUSINESS

Annual Report (1994) Grants-In-Herpetology Committee

Five awards of $500 each in three categories were made this year, as follows:

Graduate Student Research.—W. Anthony Frankino, Biology Department, Indiana University. Title: "Behavioral mediate of reproductive costs in nature: an experimental test."

Graduate Student Research.—J. Scott Keogh, Biological Sciences, University of Sydney, Australia. Title: "Phylogenetic systematics and historical biogeography of the Australian proteroglyphous snakes."

Field Work.—Sean Doody, Department of Biological Sciences, Southeastern Louisiana University. Title: "A comparative nesting study of two sympatric species of softshell turtles (*Apalone spinifera* and *Apalone mutica*)."

Field Work.—Rafe M. Brown, Biology Department, Miami University. Title: "An investigation into the systematics and biogeography of the Philippine stream frog: biochemical evolution, morphological variation and acoustical diversity in the *Rana signata* (Gunther) complex."

Conservation.—Patrick Kain, Department of Biological Sciences, Southeastern Louisiana University. Title: "Habitat use and management of the eastern diamondback rattlesnake (*Crotalus adamanteus*)."

Committee: Dawn S. Wilson (University of South Florida), Anders G. J. Rhodin (Chelonian Research Foundation), Charles W. Painter (New Mexico Department of Game and Fish), Julian C. Lee (University of Miami), Randy Jennings (Western New Mexico University), Carole L. Hom (University of California, Davis), Maureen A. Donnelly (University of Miami), A. Dale Belcher (Chair; Rio Grande Zoo).

NEWSNOTES

Second World Congress of Herpetology Abstract Volumes Available

Bound volumes of the Abstracts for the Second World Congress of Herpetology (see report of the Congress elsewhere in this issue) are available from the Congress Director. The cost is A$20 plus A$15 postage and packing. Copies of the menu (sure to become a collector's item) can be obtained for US $2 (postage included). Other products are available upon inquiry. Orders (along with checks or international money order) should be sent to: *Michael J. Tyler, Department of Zoology, The University of Adelaide, South Australia 5005, Australia.*

Directory Of Neotropical Herpetologists Now Available

A comprehensive directory of neotropical herpetologists has been published as Volume I of the Proceedings of the II Latin American Congress of Herpetologists.

The 158-page paperback lists 431 herpetologists worldwide who work on Latin American amphibians and reptiles. Each alphabetical directory entry gives the full name of the herpetologist, complete mailing address, telephone and FAX numbers, area of scientific activity, geographic region of interest, and specialization by Order.

This publication also has listings of the herpetologists by country of residence (28 countries), scientific activity (20 categories), and area of specialization by Order.

The *Directorio de Herpetologos Neotropicales* is available for US $10.00 (including air mail delivery) from: *Fundacion Fauna Andina, Casilla Postal 25, La Hechicerca, Mérida 5152, Venezuela.*

1994 California Native Species Stamp Available

California's 1994 wildlife preservation stamp—featuring a California tiger salamander (*Ambystoma californiense*) painted by artist Edward Rooks—will be on sale through 31 December 1994. Stamps can be purchased for $9.75 by mail or at California Department of Fish and Game offices in Sacramento, Redding, Rancho Cordova, Yountville, Fresno, and Long Beach.

The color painting featured on the stamp was selected from among more than 85 entries in the fourth annual native species stamp art contest. The painting was inspired by the artist's observations of a tiger salamander population at the Hastings Natural History Reservation in central California.

Also available for sale are a First Day of Issue cancelled souvenir envelope retailing at $13.50, special perforated sheets of four for $39.00, and a special collector's package including three perforated sheets of four and one limited edition non-perforated sheet of four, for $156.00. A print will be available later this year. Unsold stamps and souvenir sheets remaining after 31 December 1994 will be destroyed except for a few to be preserved for archival purposes, and the stamps allocated to the prints. Cancelled envelopes will remain available until stock is depleted.

Orders can be placed by contacting: *California Department of Fish and Game, License and Revenue Branch, 3211 "S" Street, Sacramento, California 95816, USA; tel. (916) 227-2244.* Mastercard or VISA purchases must be made by mail. For more information contact Monique Born, Research Writer, at (916) 653-4776.

A New Book from the Society for the Study of Amphibians and Reptiles

CAPTIVE MANAGEMENT AND CONSERVATION OF AMPHIBIANS AND REPTILES

Edited by James B. Murphy, Kraig Adler & Joseph T. Collins • Foreword by Gerald Durrell

This new book (written by 70 leading authorities from throughout the world representing universities, museums, conservation organizations, zoos, aquariums, and the private sector) is a current review of techniques for managing and breeding animals in captivity for purposes of conservation. The emphasis is on endangered species, special and new techniques, and on diagnosing problems, yet the coverage is comprehensive and includes a broad array of issues.

• General Issues

Herpetological Conservation from a Global Perspective
The Roles of Zoos and Aquariums

• Reproduction and Management

Nutrition of Carnivorous Reptiles
Nutrition of Herbivorous Reptiles
Effects of Temperature
Light Requirements
Veterinary Procedures for Acquisition and Release
The Physical Environment for Incubation of Reptilian Eggs
Conservation and Management of Tortoises
Chemoreception in the Feeding Behavior of Reptiles
Captive Maintenance and Lineage Senescence
Conservation of Commercially Important Reptiles
Reproductive Strategies and Conservation of Tropical Frogs
Control of Amphibian Reproduction
Reproductive Patterns of Amphibians and Reptiles
Implications of Phenotypic Plasticity
Assessing Genetic Variation in Captive and Natural Populations
Inducing Reproduction in Reptiles
Ethological Approaches to Reproductive Success
Experimental Manipulations of Clutch Size and Offspring Size

• Model Programs

Separate chapters focus on particularly successful programs. These cover salamanders, caecilians, dendrobatid frogs, hylid frogs, bufonid toads, mud turtles, Galapagos reptiles, iguanid lizards, day geckos, Old World chameleons, prehensile-tailed skinks, boid snakes, colubrid snakes, rattlesnakes, crocodilians, and tuataras.

• Future Directions

Role of the Private Sector
Future Research at Academic Institutions
Zoo Programs for Management, Breeding, and Conservation

SPECIFICATIONS: About 400 pages, 27 photographs, 50 figures, 55 tables, 1 color frontispiece, index, format 8.5 × 11 inches (21.5 × 28 cm), cloth bound. To be published November 1994.

SEND ORDERS TO: Dr. Robert D. Aldridge, Publications Secretary, Society for the Study of Amphibians and Reptiles, Department of Biology, St. Louis University, St. Louis, Missouri 63103, USA (*telephone* 314-658-3900 or -3916; *fax* 314-658-3117). Make checks payable to "SSAR"; receipt sent on request only. Overseas orders must be paid in USA funds. Orders may be charged to MasterCard or VISA (account number and expiration date required). Price list of SSAR publications and membership application available on request.

PRICES: SSAR members before 1 November 1994.....US$35
Institutions and non-members.....$58

POSTAGE: Add US$2 for orders from the USA; add $4 for orders from all other countries.

Chelonian Research Foundation Linnaeus Fund — 1993 Grant Recipients

Chelonian Research Foundation (CRF), established as a 501(c)(3) nonprofit private operating foundation in 1992, administers a turtle research endowment fund named The Linnaeus Fund. For its second annual Linnaeus Fund selections, CRF awarded four grants of $500 each on 26 December 1993. Awards granted were as follows:

BOUCHER, TIMOTHY P. Relationships between temperature and rainfall in the timing of spring emergence in the eastern box turtle (*Terrapene carolina carolina*). George Mason University, Fairfax, Virginia.

GRAHAM, TERRY E. An analysis of navigational cues and terrestrial migration of the eastern long-necked turtle, *Chelodina longicollis*, from Jervis Bay Territory, coastal New South Wales, Australia. Worcester State College, Worcester, Massachusetts.

WILSON, DAWN S. Nesting ecology of the striped mud turtle, *Kinosternon baurii*, in a central Florida population. University of South Florida, Tampa, Florida.

WINOKUR, ROBERT M. Morphology and histology of the digestive system of the threatened desert tortoise (*Gopherus agassizi*) with comparisons to other terrestrial chelonians. University of Nevada, Las Vegas, Nevada.

Linnaeus Fund awards are granted annually to individuals for specific turtle research projects, with either partial or full support as funding allows. Priority is given to projects concerning freshwater turtles, but tortoise and marine turtle research proposals are also considered. Priority is given sequentially to the following general research areas: Taxonomy and Systematic Relationships, Distribution and Zoogeography, Morphology, Ecology and Natural History. Other topics may also be considered. Priority is given to projects that demonstrate potential relevance to the scientific basis and understanding of Chelonian Diversity and Conservation Biology. Award recipients agree to publish at least partial or summarized results of the supported research in a CRF-sponsored publication, such as *Chelonian Conservation and Biology*.

Awards for 1994 are also expected to be $500 each for four research proposals. We hope that, with time, there will be increased grant support as the endowment fund grows. The annual application deadline is 15 November, with disbursement prior to 31 December. Submit applications in formal grant proposal format: title page, project objective, background and research rationale, methods, materials, total project expenses, funding requested from CRF, funding available or requested from other organizations, general timetable, bibliography, and curriculum vitae for all key personnel. Awards will be granted through a review process carried out by the Director and members of the Scientific Advisory Board of CRF. Submit applications to: *ANDERS G.J. RHODIN, Chelonian Research Foundation, 168 Goodrich Street, Lunenburg, Massachusetts 01462, USA.*

Research Opportunities At Cano Palmo Biological Station, Costa Rica

The Canadian Organization for Tropical Education and Rainforest Conservation is a Canadian non-profit education, research and conservation organization whose mission is to provide leadership in the wise use of the natural resources in the tropics. To this end, COTERC has established Cano Palmo Biological Station in Costa Rica for biological and botanical education and research.

The facilities at Cano Palmo are available for use by students, researchers and those who simply wish to experience the rainforest. The station consists of approximately 100 acres of Atlantic lowland rainforest, and is located four miles north of the small village of Tortuguero on the northeast Caribbean coast of Costa Rica, in Limon Province. The weather conditions here are favorable for the proliferation of dense tropical rainforest, providing a habitat for the most species-rich ecosystem in Costa Rica. The final list of tree species could reach 300–500. The station is situated within the boundaries of Barra del Colorado Wildlife Refuge and it is only 200 meters from the Caribbean Ocean, thus offering the additional opportunity for ocean-related studies. The adjacent beach is a major nesting site for leatherback and green sea turtles. Loggerheads and hawksbills have also been sighted. The census studies of the wildlife in the region are far from complete; however, thus far 120 species of mammals, over 300 bird species, and more than 100 species of reptiles and amphibians have been documented. Six of the seven nationally endangered reptiles occur in the region. The living facilities are comfortable and inexpensive, with three meals a day included in the fee. Guides, boats, laborers, and transportation are all available at reasonable rates.

For further information on the station, research opportunities, or COTERC, please contact: *Marilyn Cole, Executive Director, COTERC, P.O. Box 335, Pickering, Ontario L1V 2R6, Canada. Tel. (416) 683-2116; FAX (416) 392-4979.*

MEETINGS

Second World Congress Of Herpetology

Adelaide, Australia: 29 December 1993 – 6 January 1994

An account of the First World Congress of Herpetology (FWCH) was prepared by J. Eric Juterbock in his capacity as SSAR Secretary, and published in *Herpetological Review* 21(1) of March 1990. I am not sure that as the Congress Director I can provide as splendid and unbiased an account of the Second Congress. I can but try.

When the First Congress was mooted many believed that it would be held in Europe or North America simply because of the number of herpetologists in those continents. It followed that it could be assumed, for the same reason, that the Second would be held in the alternative continent. At Canterbury it became clear that with two major herpetology meetings being held each year in the USA, it was unlikely that a third major event would be attractive in that continent. Because Australia appeared to be the flavour of the month a bid was made for the Second World Congress of Herpetology (SWCH) to be held at the University of Adelaide.

The nature of the organisation of the SWCH was totally different from the FWCH. The FWCH had financial and other support from thirty leading national and international herpetological societies, and was staffed and organised by volunteers.

By such means a highly efficient Congress management was set in place. But at the outset of contemplating a bid to hold the SWCH in Adelaide, it was evident that a similar structure would not work at that venue. The reason was simply that in Australia (and particularly Adelaide) herpetologists are thin on the ground. The only way in which a Congress could be organised involved a professional team to undertake all routine administration. This structure was an integral part of the Adelaide bid. The change is quite profound. Almost all of us have devoted countless hours to the organisation of conferences, but there comes a point at which we appreciate that it is not cost effective and also is a burden. For Adelaide the 'option' was obligatory.

Planning started in early 1990. Lyall Klaffer was appointed Executive Director and Elliservice was appointed the conference organisers. We commenced operations with no funds, and without the logistic and other support provided to the FWCH. We became an incorporated body to protect those involved in the planning exercise and commenced a program of fund raising. We raised about $50,000 from the corporate sector, but were conscious of working in a declining economy; potential sponsors were reluctant to express a commitment.

As the world slipped into a period of recession the Australian dollar depreciated significantly against the U.S. dollar and many other currencies, so creating a financial climate in which travel to Australia became far more economical than had been anticipated.

But lacking funds we had no option than to borrow to provide the core to proceed; it is an expensive exercise to distribute the first brochure. The brochure itself was 'glossy' but it was funded totally from government sources devoted to promoting tourism. But its glossiness led to an assumption that we were either solvent or wasting money.

The Australian Society of Herpetologists with less than 200 members donated $2000 (which represented most of its assets) and the Congress proceeded.

Adelaide

The venue for the Congress was the city campus of the University of Adelaide. Occupying only 30 acres (12 hectares) it constitutes the smallest in Australia. But small is beautiful for a Congress because physical movement between symposia becomes simple.

The proximity between the campus and the surrounding city presented considerable advantages to the organisers. Most visitors stayed at Lincoln College about 1.0 km north of the campus, or at the nurses' quarters at the Royal Adelaide Hospital adjacent to the Congress venue.

Travel Subsidies

Fund raising to provide travel subsidies for students and other needy candidates was almost entirely an Adelaide initiative. Approximately $74,000 was raised as a result of 40 separate applications. Nineteen applicants were wholly funded by the International Science Foundation, the Australian Indonesian Association, the Consul General of Greece, the South Australian Museum Board, the Jasmin Restaurant, and the University of Queensland. A further $2500 was made available by the World Congresses of Herpetology. Most of these grants were made direct to the chosen applicants and will not therefore appear in our statements of income and expenditure. Many other registrants received institutional support to varying degrees.

Loans

A total of $19,130 in interest-free loans was borrowed from the South Australian Government, the Australian Government, the I.U.B.S., and the World Congresses of Herpetology.

Sponsorships

Major sponsors ($1000+ in cash or kind) were the Australian Society of Herpetology, I.B.M., Telecom, Western Mining Corporation, Energy Resources of Australia, the Australian National Parks and Wildlife Service, Carlton United Breweries, University of Adelaide, Australian Government, Hardy's Winery, Australia and New Zealand Bank, Dominant Chemicals, Adela Gallery, Mount Isa Mines Holdings Ltd., and the SSAR. These totalled $50,400. A further $10,000 was received in smaller sums.

Marketing

Exhibition/Trading rights were taken up by Telecom, Andrew Isles Bookshop, and Krieger Publishers. Trading tables were also hired by a large number of organisations and individuals from Australia, Germany, and the USA, and staffed by volunteers coordinated by Bruce Firth and Ingrid Belan.

The step was taken to sell goods bearing the SWCH logo: T-shirts, sweat-shirts, torches, caps, and stubby holders. These all added to the profit of the Congress and provided high quality souvenirs.

Postcards advertising the Congress designed by Paul Morton in the U.K. were printed in 1990 and sold through a variety of outlets including SSAR meetings. Australia Post produced a commemorative envelope for the first and last days of the Congress.

The SSAR published in its facsimile series *The Reptiles and Amphibians of South Australia* by Edgar R. Waite (1929). A separate print run of 1000 copies in a limp back edition was produced in Adelaide following considerable assistance from Kraig Adler.

Media Liaison

Burke and Associates was appointed media consultants to provide media coverage prior to and throughout the Congress. Many of the themes discussed at the Congress attracted international interest and the study of herpetology was promoted substantially as a consequence.

Scientific Program

The scientific program design was coordinated by Michael Bull of Flinders University and was structured differently from that of the FWCH, in that the day started with two plenary lectures held from 0900 h to 1030 h in the largest lecture area, the impressive Bonython Hall. The gathering permitted the presentation of housekeeping information in the preceding ten minutes. Then, following morning tea there were six concurrent symposia at lecture theatres within a 100 m radius of the Congress registration area.

The Plenary Lecture Themes, speakers, and chairpersons were: *Evolution*: Arnold Kluge and Roger Thorpe (Marinus Hoogmoed); *Zoogeography*: Joel Cracraft and Paul Müller (Michael Tyler); Physiology: Raymond Huey and Roger Seymour (Kraig Adler); *Ecology*: Ric Shine and Joe Travis (Murray Littlejohn); *Ethology*: Michael Ryan and Judy Stamps (Ric Shine); *Conservation and Captive Care*: Craig Moritz and Rene Honegger (Harold Cogger).

A total of 570 papers were presented in symposia or as sessions of contributed papers grouped as closely as possible into common themes. There were also 215 posters. The titles and authors of these 785 contributions are listed in the Programme and details

NARAMA—the largest display of reptiles and amphibians assembled in Australia—held at Wayville Showgrounds during the Congress.

The Second World Congress of Herpetology attracted approximately 750 attendees.

are provided in the volume of Abstracts. Copies of these publications are available for purchase. (See Newsnotes elsewhere in this issue). The poster display was organised by Ingrid Belan and Bruce Firth, and the publication of the Programme and Abstracts by Margaret Davies, Rachel Norris, and Marcus Brownlow.

Round Tables were held on Data Recording, Elapid Phylogeny, and Caecilian Biology, Workshops on Galapagos Tortoises and the Cane Toad *Bufo marinus*, an Open Forum on Commercial Trade in Reptiles and Amphibians, meetings of the Australian SSC Amphibian and Reptile Specialist Group, the Australian Society of Herpetologists, the Society for Research on Amphibians and Reptiles of New Zealand, and the SSC Directors of the Declining Amphibian Populations Task Force.

World Congress Meetings

The Executive Committee of the World Congress of Herpetology met on two occasions and a Business Meeting on one occasion. These functions were chaired by the Secretary-General, Marinus Hoegmoed. The incoming Executive Committee elected Marvalee Wake Secretary-General and Roger Avery Treasurer.

Associated Activities

For the first time in Adelaide's history all of the major cultural institutions agreed to have a single theme of special exhibitions to coincide with the Congress. The State Library produced an exhibition of herpetological literature, the South Australian Museum provided a preview of its shortly to be opened new Reptile and Amphibian gallery, the Art Gallery drew attention to amphibians and reptiles appearing on paintings, the Adelaide Zoo had an exhibition of the history of the treatment of first-aid, produced by Gael Philips, whilst a group of local herpetologists led by Geoff Coombe and Harold Ehmann assembled a large display of reptiles and amphibians (that they called Narama) in a venue at the Wayville Showgrounds on the edge of the city.

Social Program

An extensive programme of social activities was devised for delegates and accompanying persons. Legal constraints required us to employ the services of a registered tour operator, and the Convention Travel Management Company was appointed to organise and arrange all tours. These ranged from half or one day excursions to several of more than ten days.

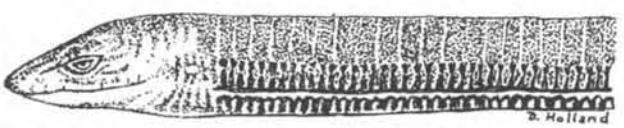
Because the Congress dates included the period between Christmas and the New Year, a major focus was the New Year's Eve Dinner. A fleet of buses transported folk from the centre of Adelaide to the Hardy Winery at Reynella some 20 km south of the city. The night was cool but the organisation superb. A staff of 80 provided South Australian wines, kangaroo steaks, etc., but the menu promised more. Following the 'Cordon Noire' reputation

of Ric Shine abetted by Gordon Grigg (Cordon Noire is Cordon Bleu blackened a bit), our guests began to understand that the organisers could not always be trusted. The menu selections included:

Soup: Filesnake Slough Consomme. A delightful blend of freshly shed skin from *Acrochordus arafurae*, together with whipped cream and chocolate-coated gastroliths from juvenile Saltwater Crocodiles. Guaranteed to serve as effective ballast during diving.

Entree: Froglegs au Adelaide. Tender hind limbs of *Limnodynastes*, specially cultured in the sedimentation tanks at the University of Adelaide's sewerage treatment plant. This marinade imparts a unique flavour to the gastrocnemius muscle, and the piquancy is enriched with a subtle blend of prostaglandins from the gastric mucosa of *Rheobatrachus vitellinus*.

Main Course: Grilled Fillet of Sleepy Lizard. A traditional Australian favourite, from our hand-reared stock at Flinders University. All of the lizards used are guaranteed to be the result of monogamous matings, slaughtered at the end of sustained metabolic experiments so that their muscles are tenderised by maximum lactate accumulation. Served with autotomised *Nephrurus* tails, grilled to perfection, each with their own terminal knob for convenience in handling. (When in season).



Dessert: Spermatophore Custard. Chocolate-covered spermatophores from North American plethodontids, swimming in sauce made from special "kin recognition" pheromones mixed with liver homogenates rich in mitochondrial RNA. Gene sequences of the RNA available from the chef, on request. The purity of these preparations has been assayed by monitoring tongue-flick rates of newborn herpetologists.

The birth of the New Year was heralded by a kilted Scot (John Wombey) playing his bagpipes. Riotous dancing continued until the wee hours, and guests understood why that day was bereft of a scientific program more taxing than looking for reptiles.

South Australia 5005, Australia.

LEGISLATION & CONSERVATION ALERT

U.S.A.: U.S. Fish and Wildlife Service: The U.S. Fish and Wildlife Service has designated critical habitat for the Mojave population of the desert tortoise (*Gopherus agassizii*), a species federally listed as threatened under the Endangered Species Act of 1973, as amended (Federal Register, Vol. 59, No. 26, 8 February 1994). This final rule became effective on 10 March 1994 and designates 6.4 million acres in Arizona, California, Nevada, and Utah. Critical habitat is defined as those lands that possess physical or biological features essential to the conservation of the species and which may require special management considerations or protection. Critical habitat receives protection under Section 7 of the Endangered Species Act with regard to actions carried out, funded, or authorized by a Federal agency. For further information contact: *David L. Harlow, Field Supervisor, Nevada Field Office, USFWS, 4600 Kietzke Lane, Building C-125, Reno, Nevada 89502, USA. Tel. (702) 784-5227.*

SSAR Grants-in-Herpetology

Proposals are now being accepted for the 1995 SSAR Grants-in Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

2. FIELD RESEARCH. Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include in-situ behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.

3. LABORATORY RESEARCH. Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

4. HERPETOLOGICAL EDUCATION. Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on an herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president.

5. TRAVEL. Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR with the exception of those applying for support of regional herpetological society projects. Membership dues must be paid (to SSAR Treasurer) no later than 31 December 1994 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) BACKGROUND AND OBJECTIVES of the proposed project. (B) METHODS of carrying out the project. (C) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). (D) BRIEF RESUMÉ of the applicant or project coordinator. (E) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages excluding resumé and budget.

Applicants must designate to which of the five categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than 31 DECEMBER 1994 to be considered. Please include office and home phone numbers, as well as fax number if available. It is often necessary to contact applicants quickly. Failure to meet the guidelines may result in elimination of a proposal from consideration. The awards will be announced by 1 April 1995. Successful applicants will be expected to submit a written report of the results of this support within a reasonable amount of time after the project year is completed. They are also encouraged to submit the results of research projects for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Dale Belcher, Chair, SSAR Grants-in-Herpetology, Rio Grande Zoo, 903 Tenth St. SW, Albuquerque, New Mexico 87102-4098, USA. Tel. (505) 843-7413, FAX (505) 842-7281.*

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number and/or size of awards. Your tax-deductible contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

IN MEMORIAM

Mangven Chang (1903–1993): Pioneer Herpetologist Of China

Professor Mangven Chang *(Pinyin spelling:* Mengwen Zhang), one of the leading Chinese herpetologists of the 20th century, died in Shanghai on October 2, at the age of 89. Chang was one of that group of Chinese biologists who earned their doctorates overseas prior to the Second World War and then returned to China in order to lead the country's modernization of biological research and teaching.

Chang was born in Ningbo City, Zhejiang Province, on May 7, 1903. He was a student of the famous biologist Chih Ping (Zhi Bing) at Southeastern University in Nanjing (now Nanjing University), and graduated in 1926, after which he became associate professor in the School of Agriculture at Peking University where he taught zoology and anatomy. In 1934, he went to France to earn his doctorate under Louis Roule at the University of Paris at which time he was also associated with Fernand Angel of the Muséum National d'Histoire Naturelle. Chang's thesis, completed in 1936, was published in book form the same year, entitled "Contribution à l'Étude Morphologique, Biologique et Systématique des Amphibiens Urodèles de la Chine" (reprinted by Society for the Study of Amphibians and Reptiles in 1968). This was the first comprehensive review of the salamanders of China.

Chang returned to China in 1937 and held a number of positions, successively, at Zhejiang University, Fudan University (at the Chongqing campus, where he was chairman of biology), Heilongjiang University, Harbin Normal University, and finally at East China Normal University in Shanghai. Chang had many prominent herpetological students, including Huiqing Gu, Buqing Hu, Zhengyi Huang, Zhixun Li, Kentang Zhao, and Yu Zong, who went on to productive careers of their own.

In addition to his book on salamanders, Chang published many significant monographs on amphibians and reptiles, in particular about those species native to Sichuan and Zhejiang provinces. He published several general books (on vertebrate zoology, 1987; comparative anatomy of vertebrates, 2 volumes, 1986–1988; history of biology, 1956). He was an outstanding teacher, actively lecturing on many biological topics. He was one of the founders of the Chinese Zoological Society, served as president of the Shanghai Zoological Society, and was Honorary President of the Herpetological Society of China at the time of his death. His contributions to Chinese biology and particularly to herpetology were fundamental and he is justly remembered as a pioneer herpetologist of China.

ARTICLES

Exotic Larval Bullfrogs (*Rana catesbeiana*) As Prey For Native Garter Snakes: Functional And Conservation Implications

The ability of an exotic species to invade and establish in a new community is determined in part by its competitive status relative to native species (Brown 1989), and in part by its vulnerability to local predators. Bullfrogs (*Rana catesbeiana*) are currently invading the South Fork of the Eel River in northern California. Along reaches where they are common, especially at large pools, native anurans are rare or absent (S. J. Kupferberg, unpublished data). Experimental results suggest that larval competition between bullfrogs and two native species, the Pacific treefrog (*Pseudacris regilla*), and the foothill yellow-legged frog (*Rana boylii*), may contribute to exclusion of these natives from previously occupied stream habitat (Kupferberg 1993). While garter snakes commonly eat larval and metamorphic anurans (Arnold and Wassersug 1978), bullfrog larvae can exceed the mass of native anurans by an order of magnitude. The question arises, will western aquatic garter snakes (*Thamnophis atratus*), the most common snake at the site, be an effective predator of bullfrog tadpoles and metamorphs?

Here I report feeding events in which *T. atratus* eat large bullfrog tadpoles that had over-wintered. In addition, I present data on snake size distribution to illustrate that large individuals likely able to consume bullfrog tadpoles are uncommon. Even the largest snakes observed had considerable difficulty swallowing second-year bullfrog tadpoles. The relatively large prey size leads to handling behavior akin to tool use. Prey shape, in particular the diameter of bullfrog tadpoles' heads and bodies, rather than their overall mass, may reduce bullfrog vulnerability to snake predation.

Field work was conducted in the vicinity of the Northern California Coast Range Preserve, Mendocino Co., California (39°44'N, 123°39'W). Sizes of snakes and anuran larvae were recorded when animals were being collected for experimental predator/prey and competition investigations between 1990 and 1992. Wide size ranges of animals were collected and then the most similarly sized individuals were used for experiments; data reported here are for the full range of those collected. Snakes were captured by hand in June and July, 1990 and 1991, which might have biased the size distribution towards larger snakes because neonates do not appear until August. This however would yield a conservative estimate for the purpose of my hypothesis. The sizes of over-wintering *R. catesbeiana* tadpoles come from those caught by hand using dip nets while wading or snorkeling on 8 June 1992. Tadpoles were weighed using an electronic field balance to the nearest 0.1 g. Observations of snake predation on bullfrogs were made opportunistically during the course of field surveys and experiments with tadpoles, June through September, 1990–1993.

Only the largest snakes ate large second-year bullfrog tadpoles (Fig. 1) and I did not observe snake predation on first-year larvae. The mean mass of second-year bullfrog tadpoles (20.2 ± 6.8 g, range 7–45 g, N = 70) far exceeds the maximum size attained by tadpoles of native species (1.6 g for *R. boylii*, 0.9 g for *P. regilla*) at the site. On two occasions I observed snakes in the process of consuming tadpoles, and on three occasions I offered tadpoles to snakes to better observe the attack-capture-ingestion process (Table 1). Tadpoles removed from the water and placed on the shore in close proximity to foraging snakes were quickly attacked.

The difficulty that *T. atratus* has in handling larval bullfrogs is exemplified by an unusual behavior I observed on one occasion when a snake pushed a tadpole against a rock to facilitate engulfing the partially ingested prey. On 10 July 1993 (1630 h), I placed

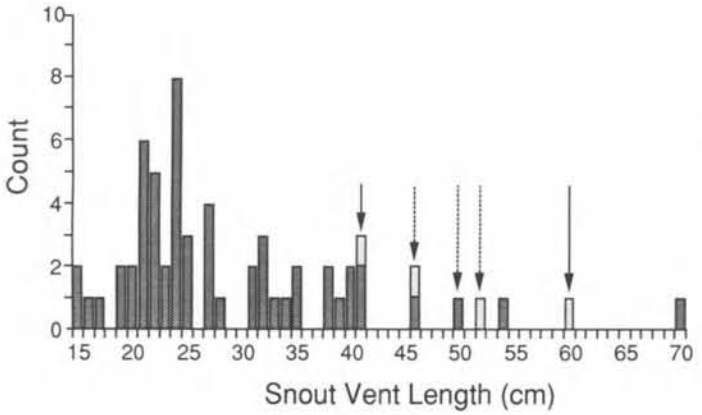

FIG. 1. Size distribution of *Thamnophis atratus* (mean SVL = 28.7±10.3 cm, N = 57; mean mass = 12.7±12.3 g, N = 53). Arrows point to sizes of snakes observed consuming larval/metamorphic *Rana catesbeiana* prey. Solid arrows indicate natural observations, and dashed lines indicate that prey were offered to the snake. Dark bars indicate snakes that were captured during summers 1990 and 1991, and light bars indicate snakes observed during subsequent years.

a *R. catesbeiana* tadpole by the edge of a stranded side pool (22 m x 6.5 m x 0.25 m deep), where a *T. atratus* was foraging. Within one minute the snake attacked and bit the tadpole's tail. The tadpole attempted to swim away, the snake chased it, bit the tail again and held on as the tadpole thrashed from side to side. After another minute the tail was almost completely consumed. Swallowing began underwater at the capture site, but it became difficult for the snake to continue swallowing when it reached the round tadpole body. The snake swam 1.5 m to the opposite bank, hauled one third of its body out of water, wedged itself between three rocks, and began swallowing the body of the tadpole. Two boulders were opposite each other, 11 cm apart, and a third boulder made a headwall. The gravel substrate between the rocks sloped up towards the headwall rock. The snake braced its body between the two parallel boulders, with points of the s-curve against each rock. Its head was up-slope at the headwall rock. Periodically over a twenty minute period the snake pushed the snout of the tadpole against the headwall rock while continuing to brace with the sides of its body and made slow progress in advancing its jaws over the body of the tadpole. When not pushing against the rock the snake lifted its head and tilted it backward. By 1655 h, the tadpole's snout was at the snake's snout, but the sides of the tadpole's deformed body protruded from the sides of the snake's mouth. The tadpole was fully consumed five minutes later. On the occasion when a bullfrog tadpole prey was offered to a garter snake in captivity, handling time was excessive, 2 h, perhaps because in the confines of a round bucket, the snake could not employ any of the behaviors described above.

These observations show that *T. atratus* can eat bullfrog tadpoles, but these snakes are not likely to be effective bullfrog predators. Snake size distribution suggests that most are too small to feed on second-year larvae and even the largest individuals had difficulty handling bullfrog prey. Those snakes which can attack bullfrog tadpoles are likely to have low overall feeding rates when single large prey items are consumed. With higher surface to volume ratios, large prey would likely be digested more slowly thereby decreasing the rate of prey consumption and reducing per capita risk. Long handling times also increase the risk of predation on snakes by avian predators. Additionally, *T. atratus* displays an ontogenetic shift in foraging mode away from tadpole prey towards fish and salamander prey as snake size increases (Lind 1990). At a creek containing only *R. boylii* as anuran prey, tadpoles constituted 60% of neonate *T. atratus* stomach contents, and only 26% and 29% of juvenile and adult stomach contents (Lind 1990). *T. atratus* take large Pacific giant salamanders (*Dicamptodon tenebrosus)* up to 133 mm SVL and 88% of snake mass (Lind and Welsh 1990) which are comparable in size and weight ratio to large bullfrog larvae (Table 1). Shape, however, especially with respect to roundness, is not comparable between salamanders and bullfrog tadpoles. The ratio of prey diameter to a snake's head diameter is the aspect of prey size likely to determine a snake's ability to ingest prey (Greene 1983). Specialization on round prey necessitates morphological modifications that would increase gape, as in the African egg-eating snakes (Gans 1974). It is also interesting to note that where bullfrogs are native and common, they do not appear in water snake (*Nerodia sipedon*) gut contents, whereas other co-occurring smaller ranids have historically constituted a portion of water snake diet (King 1993). Future investigations should focus on whether *T. atratus* will select prey by size or by species and whether there will be a shift in the snake size distribution.

TABLE 1. *Thamnophis atratus* feeding events on larval *Rana catesbeiana* prey (—indicates no data).

Date	Tadpole Size SVL, TL (cm)	Tadpole ≈ Stage	Snake SVL (cm)	Location/timing of observation	Handling time (min)
20 Jul 1991	5.5, 9	(41)43-44	50 (59 g)	Snake in plastic bucket; live prey enclosed.	120
21 Sep 1992	7, —	43-44	60	Snake on a rock in a riffle; in progress.	—
10 Jul 1993	4.5, 12	37-39	52	Snake in water; prey offered at bank.	5
10 Jul 1993	3.8, 8.5	37-39	46	Snake in water; prey offered at bank.	30
13 Aug 1993	5.5, 13	39-40	41	Snake in grass at edge of pool; in progress.	—

Acknowledgments.—Valuable assistance in field work was given by L. Cornelison, R. Fewster, C. Lowe, K. Meier, M. Parker, and M. Power. I thank H. Greene, M. Parker, and M. Power for valuable comments on earlier drafts of the manuscript. These observations were made possible by a NASA Global Change Fellowship and NSF BSR 9100123 to Mary E. Power.

Distribution And Abundance Of *Perochirus ateles* (Gekkonidae) In The Mariana Islands

Perochirus ateles (Micronesian gecko) has a fairly large range that includes the Caroline and Mariana Islands, and Marcus Island (Brown 1976). In the Marianas, Brown examined specimens from Cocos, Guam, and Tinian Islands, implying that the range is the southernmost islands in the archipelago. Museum records and recent surveys of most of the islands in the Marianas (Rodda et al. 1991) confirmed the presence of this species only on Cocos, Guam, Tinian, and Saipan Islands, all of which are the southernmost islands in the archipelago. Despite surveys on Rota (an island between Guam and Tinian) in 1988 (Wiles et al. 1990) and in 1991 (McCoid, unpub. data), *P. ateles* was not recorded.

With the exception of Cocos Island, museum data and survey information indicate that *P. ateles* is rare, uncommon, or extirpated on islands in the Marianas where it has been recorded. On Guam, the last museum record is 1978 and virtually continuous surveys from 1984 to the present have not revealed the presence of this species. On Tinian, the only known specimen was collected in 1946 and recent surveys (Rodda et al. 1991; Wiles et al. 1989) have not yielded any additional sightings or specimens. On Saipan, three specimens were collected between 1979 and 1984 and there have been several reliable sightings subsequently (D. Stinson, pers. comm.). On Cocos Island, a fringing atoll approximately two km south of Guam, we found *P. ateles* to be a conspicuous and abundant member of the nocturnal herpetofauna. In the area (a resort that occupied the eastern 1/3 of the island) that we frequently surveyed during 1989 and 1990, *P. ateles* formed about 5% of the gekkonid community (63 captures (MJM Private Collection) in 30 h of searching). It was also abundant on the remainder of the island (1/3 of which was relatively undisturbed atoll forest dominated by *Casuarina*, *Hernandia*, and *Cocos*), but surveys were infrequently conducted in this area of the island.

Sabath (1981) characterized *P. ateles* as a forest habitat specialist. Rodda et al. (1991) adopted this view and stated that this species occurred in relatively undisturbed forests or in situations adjacent to forests. On Cocos Island substantial numbers of *P. ateles* occurred on buildings and lighted porches in areas of moderate human activity. We conclude that this species tolerates a fair amount of habitat alteration.

The ability of *P. ateles* to persist despite habitat destruction and environmental perturbations is emphasized by the Cocos Island population. This island has a surface area of approximately 37 ha and underwent the development of a coconut plantation prior to WWII, construction of a U.S. military installation (formerly occupying approximately 1/4 of the island), two resorts (occupying a total of 1/2 the island), and at least three typhoons (see below) since 1949 that have overwashed the island (Neubauer and Neubauer 1981; per. obs.). Only about one third of the island remains as regenerated atoll forest. In late 1990 and 1991, typhoons hit Guam and Cocos Island causing tremendous damage on both islands. The resort was destroyed by the cumulative effects of the typhoons and subsequent clearing by a private company that controlled the resort. The remaining two thirds of the island were completely defoliated of all broadleaf vegetation and an estimated 50 to 60% of the trees were lost. Due to radical alteration of the habitat we were unable to quantify the post-typhoon gekkonid population using the survey techniques employed earlier. However, no lizards of any species were sighted at the resort end of the island after debris clean-up was initiated by the resort in early 1992. Because at least one third of the island no longer harbored any lizards and a substantial portion of the remaining habitat was lost, a conservative estimate is that a 30+% population decline of *P. ateles* occurred on Cocos Island as a result of the storms and subsequent clean-up activity.

Reasons for rarity on the other islands have not been established. Although Wiles et al. (1989) speculated that the absence of *P. ateles* from Tinian was due to extensive clearing for agriculture, suitable habitat (primary, secondary, and beach strand forest) remains on approximately 28% of the island. Unless there was an island-wide decline in all habitats, *P. ateles* should have persisted in these areas despite large scale ecological disturbances over most of the island. The single known specimen from Tinian was collected after the termination of large scale agricultural practices and construction associated with WW II. Specimens from Saipan have come from a number of situations, including from inside a house, but the few recent sightings all involve relatively undisturbed limestone forest. Since Saipan did not experience the extensive agricultural development that Tinian did, substantial tracts of primary and secondary forest still exist. Presence on Rota is expected, as approximately 60% of the island is primary typhoon forest (Wiles et al. 1990) and the island is bracketed by known populations. However, if the *P. ateles* population on Rota had experienced an island-wide decline similar to that presumed for Tinian and Saipan, failure to record this species would not be unexpected. In contrast to the more northern islands in the Mariana archipelago, Guam had once substantial populations of *P. ateles*. Sabath (1981) estimated that in the late 1960s *P. ateles* comprised 11–18% of the gekkonid fauna in beach strand and limestone forest, respectively. By the mid-1980s, the species was extirpated from Guam, possibly due to predation by the introduced brown tree snake, *Boiga irregularis* (Rodda and Fritts 1992).

It is unlikely that introduced species have played a role in large-scale population declines on Rota, Tinian, and Saipan. Although an introduced gekkonid has been shown to adversely affect a native species (Petran et al. 1993), confamilials (e.g., *Hemidactylus frenatus*) have never been shown to cause, through competition, the extirpation of native reptiles (Case and Bolger 1991). The pattern of island occupation by other potentially detrimental introduced species (*Rattus* spp. and *B. irregularis*) does not correlate with known or suspected populations of *P. ateles*. Rats are, or were, abundant on Guam, Rota, Tinian, and Saipan, but also occur on Cocos. *Boiga irregularis* occurs only on Guam. *Suncus murinus*

(a shrew) is introduced in the southern Marianas, but is not a likely factor in population declines of arboreal gekkonids as this shrew does not climb very well (Barbehenn 1962).

The prognosis for *P. ateles* in the Mariana Islands is not favorable. Considering the current low population density on Saipan, the possible extirpation on Tinian, the failure to record the species on Rota, the definite extirpation on Guam, and the substantial population reduction on Cocos, *P. ateles* should be viewed as a rare species in the Mariana Islands. The greatest historical population densities occurred on Guam and Cocos and not on more northern islands. Reasons for the absence on Rota and Tinian, and rarity on Saipan are currently unknown. The densest population will continue to be on Cocos Island, but future typhoon damage may further destabilize this population. Most importantly, the possible establishment of *B. irregularis* on Cocos Island from Guam (there have been several sightings of *B. irregularis* on Cocos) will likely extirpate the last remaining dense population of *P. ateles* in the Mariana Islands. *Perochirus ateles* is now protected by the Commonwealth of the Northern Mariana Islands (all islands north of Guam) and has been proposed for protection by the Territory of Guam.

Acknowledgments.—G. H. Rodda and two anonymous reviewers generously commented on a draft of the manuscript. D. Stinson (Commonwealth of the Northern Mariana Islands) supplied information. Portions of this study were supported by the Endangered Species Conservation Program, Project E-4 (to Guam).

Eggs, Hatchling Sizes, And Oviposition Sites Of Lizards On Guam, Mariana Islands

Early life history information on many species of lizards in the western Pacific, particularly the Mariana Islands, is poorly known. A single study (Sabath 1981) estimated clutch size in some gekkonids on Guam. To fill in this information gap, eggs and hatchlings (N = 252) of 13 of the 15 species of lizards occurring on Guam, or neighboring Cocos Island, were collected. No information was garnered on the remaining two species (*Nactus pelagicus* and *Lipinia noctua*) as they have either been extirpated or occur at very low densities (Rodda et al. 1991). Data were collected between 1988 and 1992. Eggs were incubated under ambient temperatures (25–30°C) and measurements taken the day of hatching. Egg measurements were taken throughout incubation on species with parchment-shelled eggs (scincids) and once during incubation on calcareous-shelled eggs (gekkonids). Time of egg measurement for parchment-shelled species (just prior to hatching or at deposition) is noted in the text. If incubation was unsuccessful, or eggs were not available, the smallest known specimens with umbilical scars were used to infer approximate size at hatching.

Scincidae

Carlia fusca—This abundant, introduced skink (McCoid 1993a) is ubiquitous in all habitats on Guam. Sites of oviposition are beneath virtually any object, ranging from discarded trash to vegetation root masses, that has been in place long enough to alter microhabitats to provide adequate temperature and humidity incubation requirements. Communal nesting has been observed with *Gehyra oceanica*, *Anolis carolinensis*, and *Emoia caeruleocauda*. Clutch size is an invariant two and eggs are parchment-shelled, ovate, and have a mean length at deposition of 11.96 mm (SD 0.882, N = 13). Hatching is 34 to 35 days and eggs gain size and weight during incubation (mean % weight gain during full-term incubation 37.5, SD 26.541). Mean hatchling SVL is 23.42 mm (SD 0.98, N = 129).

Cryptoblepharus poecilopleurus—While this species has never been recorded on Guam (Rodda et al. 1991), it is abundant on Cocos Island, a fringing atoll approximately 2 km south of Guam. On Cocos Island, this arboreal species is most conspicuous on the windward (east) side where it commonly occurs in *Casuarina equisetifolia* groves. While no eggs have been found on Cocos Island, a captive female deposited two parchment-shelled, ovate eggs (mean length 11.8 mm). Schwaner (1980) found a mean egg length from American Samoa of 10.1 mm. McCoy (1980) stated an invariant clutch size of two for the Solomon Islands, but necropsied females (N = 7) from Cocos Island contained one or two oviductal eggs (mean clutch size 1.51). The Cocos clutch size data are similar to those presented by Schwaner (1980) for American Samoa. No hatchlings were obtained from incubated eggs, but two free-living lizards (20.6 and 21.7 mm SVL) with prominent umbilical scars were collected. Observations of this species on Cocos Island included only rare terrestrial movements, suggesting that eggs may be deposited in the root masses of occupied trees.

Emoia atrocostata—This is another species never recorded on Guam (Rodda et al. 1991), but is relatively abundant on Cocos Island. The species is restricted to the tidal splash zone on the windward side of the island. No eggs or hatchlings have been collected, but several small *E. atrocostata* (estimated 20–25 mm SVL) have been observed. Greer (1968), Alcala (1986), and McCoy (1980) reported a clutch size of two from other island groups and egg deposition above the tidal zone. Dense thickets of *Pemphis acidula* border the splash zone on Cocos Island and are a likely area for egg deposition.

Emoia caeruleocauda—Known egg deposition sites on Guam are beneath concrete bricks and fallen logs. McCoy (1980) found eggs

in ground debris in the Solomon Islands. Communal nesting on Guam with *Carlia fusca* and *Gehyra oceanica* has been observed. Greer (1968) and McCoy (1980) indicated an invariant clutch size of two and necropsies of females (> 40 mm SVL, N = 25) from Guam (based on oviductal eggs and secondary follicles) corroborate this pattern. Ten ovate and parchment-shelled eggs (four clutches of two and two singles) (mean egg length within one day of hatching 12.25 mm, SD 0.777, mean width 9.45 mm, SD 0.058, N = 4) were incubated from three to 26 days and mean SVL of hatchlings was 22.75 mm (SD 0.817, N = 10).

Emoia cyanura—A sighting of this species (Kami et al. 1974) is the only record for mainland Guam, but this species is relatively common on Cocos Island. No eggs were collected, but a 24.6 mm SVL specimen possessed a prominent umbilical scar. Greer (1968) reported a clutch size of two, but Schwaner (1980) in American Samoa and Zug (1991) in Fiji found a mean clutch size of less than two. Hatchling size ranged from 22 to 23 mm SVL in Fijian specimens and mean hatchling SVL in Samoan specimens was 22.0 mm. Based on necropsied adult females from Cocos Island (N = 4), clutch size is an invariant two. Egg deposition sites on Cocos Island are probably in debris and beneath logs.

Emoia slevini—This is the only endemic reptile in the Mariana archipelago and natural history information is limited to a short description of habitat (Brown 1991). Because this is primarily a terrestrial forest-dwelling species, egg deposition sites are probably similar to other forest-dwelling *Emoia*. No eggs have been collected, but a specimen from Cocos Island (SVL 32.0 mm) possessed a prominent umbilical scar. Eggs were observed (Falanruw 1989) on Asuncion Island (Mariana Islands) but no description was provided.

Gekkonidae

Gehyra mutilata—Sites of egg deposition on Guam were in discarded feed bags and behind wooden slats of an abandoned shack. Zug (1991) found eggs on Fiji in flower bracts, leaf axils, beneath bark, and in buildings. Fitch (1970) reported an invariant clutch size of two, but Schwaner (1980) found clutches of one or two in American Samoa. Clutch size on Guam is an invariant two (Sabath 1981) and eggs (mean length 9.5 mm, mean width 8.2 mm, N = 2) are calcareous, subspherical, and adhesive. Mean egg mass of Guam specimens was 0.31 g (SD 0.023, N = 3) and mean hatchling SVL 20.9 mm (SD 0.942, N = 9). Brown and Alcala (1978) reported hatchling size range of 18.5–23.0 mm SVL in the Philippines.

Gehyra oceanica—Literature reports of egg deposition sites indicate an apparent degree of opportunism (McCoy 1980; Zug 1991) and conspecific communal nesting (Zug 1991). On Guam, a clutch (along with egg shards from a previous clutch) was found buried in soft dirt with clutches of *Carlia fusca* and *Emoia caeruleocauda*. Egg shards have also been found buried in guano heaps of the cave-dwelling island swiftlet (*Aerodromus vanikorensis*). Eggs (mean length 13.85 mm, mean width 12.8 mm, mean mass 1.36 g, N = 2) were calcareous, subspherical, and non-adherent. Schwaner (1980) reported clutch sizes of 1–4 on American Samoa and Sabath (1981) reported clutch sizes of 1–2 for Guam. The mean hatchling SVL of the above clutch was 32.6 mm.

Hemidactylus frenatus—This common human commensal is abundant on Guam and has an invariant clutch size of two (Schwaner 1980). Eggs (mean length 8.62 mm, SD 0.325, mean width 7.59 mm, SD 0.342, N = 26) are subspherical, calcareous, and non-adhesive. Schwaner (1980) reported incubation of 77–88 days in American Samoa and Brown and Alcala (1957) 70+ days in the Philippines; incubation period on Guam was 53–54 days. Communal nesting in non-urban situations with *Lepidodactylus lugubris* in plant axils and holes in trees has been observed. In urban situations on Guam, *H. frenatus* will deposit loose eggs in the bottom frames of sliding windows while *L. lugubris* will glue eggs along the upright frames of the same windows. *Hemidactylus* will also opportunistically deposit eggs in a variety of novel situations, including in stacks of dishes, beneath cushions on a couch, and inside televisions, radios, and videotape players. Mean egg mass of specimens from Guam was 0.27 g (SD 0.032, N = 66) and mean hatchling SVL was 20.32 mm (SD 0.832, N = 66). These data closely resemble the summary presented by Zug (1991).

Lepidodactylus lugubris—This parthenoform is typified by a clutch size of two (McCoy 1980; Zug 1991) but may lay a single egg (Sabath 1981; Zug 1991). Large females (> 45 mm SVL) on Guam may also contain three oviductal eggs. Conspecific communal nesting has been reported (McCoy 1980; Zug 1991) and is common on Guam. Communal egg laying on Guam has also been observed with *Hemidactylus frenatus*. Nesting sites on Guam are similar to those reported in the literature (McCoy 1980; Zug 1991) and include tree holes as little as 13 cm from the ground. Eggs (mean length 9.24 mm, SD 0.406, mean width 6.99 mm, SD 0.247, N = 10) are ovate, calcareous, and adhesive. Gibbons and Zug (1987) reported a mean egg mass of 0.4 g for Fiji and 0.23 g for Tonga; mean egg mass on Guam was 0.25 g (SD 0.03, N = 19). Brown and Alcala (1978) reported a hatchling SVL range of 15.5–17.6 mm in the Philippines and Zug (1991) a mean hatchling SVL of 16 mm. Specimens from Guam had a mean SVL of 18.9 (SD 0.614, N=19). McCoid and Hensley (1991) reported that 76% of *L. lugubris* encountered were clone 'A' (fide Ineich 1988). All hatchlings reported on here from Guam were clone 'A.'

Perochirus ateles—This Micronesian endemic has a reported clutch size of 2–3 (Sabath 1981). A single captive female laid two subspherical, calcareous, adhesive eggs. No measurements were taken, but eggs were larger than dimensions given for *Hemidactylus frenatus* and smaller than for *Gehyra oceanica*. Three probable hatchlings (mean SVL 19.9 mm, SD 0.458) were collected on Cocos Island.

Polychridae

Anolis carolinensis—After the introduction on Guam in the mid-1950s (McCoid 1993a), the entire island was colonized, although predation by introduced *Boiga irregularis* currently restricts distribution to urban areas. Clutch size is one (Hamlett 1952), although a single necropsied female contained two oviductal eggs. A single parchment-shelled, ovate egg (no measurements) was found, along with several eggs of *Carlia fusca*, in loose dirt beneath an ornamental tree. Incubation was 30 days and hatchling SVL was 21.0 mm.

Varanidae

Varanus indicus—Eggs from captive females on Guam have never been successfully incubated. Data from DOR females (McCoid 1993b) suggests that clutch size for medium to large females (≥ 380 mm SVL) is at least 10 eggs. The only known oviposition site (containing egg shards only) is in guano deposits of a cave-dwelling bird (*Aerodromus vanikorensis*). Oviductal eggs were oblong, parchment-shelled, and ranged from 40.5 to 46.7 mm in length (McCoid 1993b).

Acknowledgments.—Portions of this study were funded by the Endangered Species Conservation Program, Project E-4. Rebecca Hensley kindly reviewed a draft of the manuscript.

POINTS OF VIEW

Editor's note: The following article is part of a recently published monograph [Campbell, J. A., and D. R. Frost. 1993. Anguid lizards of the genus Abronia: *Revisionary notes, descriptions of four new species, a phylogenetic analysis, and key. Bull. Am. Mus. Nat. Hist. 216. 121 pp. (pp. 53-56 reprinted here)].*

Conservation Biology

Although *Abronia* represents more than half of gerrhonotine anguid lizard species diversity (approximately 25 out of 45 species), restricted distributions and habitats disturbed or destroyed by human development have made most members of the genus *Abronia* among the most endangered species of lizards in the world. Moreover, because cloud forest species tend to be restricted to single or adjacent cloud forests, several undescribed species of *Abronia* likely have already become extinct with the human destruction of cloud forests on several of the volcanoes of southern Guatemala and adjacent El Salvador. As an example of this habitat destruction, the ranges of *A. mitchelli* (known from a single specimen) and *A. fuscolabialis* (known from only five specimens) in Oaxaca, Mexico, are currently being clear-cut, much of it apparently illegally. This destruction is irreversible and inexorable; there is ample evidence that officials who stand in the way of the cutting of Oaxacan forests are at risk of assassination by logging interests (Katz 1992).

Our decision to address the issue of imminent extinction of *Abronia* was not taken lightly. Systematic biologists have been slow learners when it comes to the political realities of "biological conservation," and it has become very clear that the usual consequence of biologists supplying information on endangerment of species is the regulation of biologists (and therefore of information acquisition) and not habitat protection (Hedges and Thomas 1992; personal observ.). As the world fauna and flora becomes increasingly endangered by human overpopulation (the primary manifestation of which is habitat degradation), the freedom of biologists to survey rapidly disappearing natural faunas and floras has been increasingly restricted. Regardless of this counterproductive effect of species-based regulation, in the past two decades many species of amphibians and reptiles have been listed by federal and state governments, or, more onerously and less effectively, by the Convention on International Trade in Endangered Species of Flora and Fauna (CITES). Particularly in tropical countries, this regulation has had negligible influence on habitat destruction and, with the exception of a few large and/or photogenic mammals and birds, extirpation of species.

Once species are legally protected, study by biologists usually requires expensive and/or difficult-to-obtain permits. In effect, legislation limits access to regulated animals to those most able to pay (i.e., commercial interests) or to those whose activities indirectly extirpate species (e.g., subsistence woodcutters). For example, at the time of this writing, scientific collecting permits for non-nationals in Mexico are $1000/permit, clearly far above their administrative overhead cost, and obviously aimed at restricting access of non-Mexican scientists to that rapidly disappearing fauna. There appears to us to be no effective limitation of habitat destruction in that country. The extinction of the frog *Rana tlaloci* (O. Flores-Villela, personal commun.) within 10 years of its discovery (Hillis and Frost 1985), due entirely to the effects of urbanization of central Mexico, is an example of this regulatory asymmetry. That is, it would have cost a non-Mexican biologist $1000 to legally collect a single specimen of *Rana tlaloci* from the canals of Xochimilco, even as the unregulated effects of urbanization were driving them extinct. Although we note regulatory conditions in Mexico, where many *Abronia* occur, regulatory conditions in other countries (including the United States[8]) and internation-

ally are frequently the same or worse, so these are widespread problems. With respect to international regulation, in recent years we have witnessed the CITES listing of dendrobatid frogs on the basis of no evidence of endangerment whatsoever (C. W. Myers, personal commun.; see also Mrosovsky 1988, and Bringsøe 1992), as well as the U.S. delegation to the 1987 CITES convention vote against the delisting of an Australian mammal, even though there was no evidence of trade in the species, Australia initiated the proposal for delisting, and Australian laws were considered adequate for its protection (DRF, personal observ.). In other instances, conservation legislation such as CITES listing or the Endangered Species Act appears to be largely irreversible and in some instances continues to protect some species for which a secure future has been won (Enderson 1992), thus wasting valuable funding and effort that might be allotted to those species and habitats in critical need of protection.

At a more local administrative level, U.S. state wildlife agencies often deny biologists access to "endangered" species (e.g., *Batrachoseps wrighti* in old-growth forests in Oregon) while other regulatory agencies may be promoting destructive development or logging in the same areas, although this development causes many deaths of these protected organisms. The state of California protects the sand dune-restricted species *Uma inornata*, but allows access of all-terrain vehicles in their habitat with murderous results[9] (Brattstrom 1988; Brattstrom and Bondello 1983). It is obvious to us, and many others (Gans 1992; Hedges and Thomas 1992) that the only viable approach to maintaining self-renewing natural populations of many organisms, including *Abronia*, is to protect blocks of natural environments, not by attempting to protect individuals or particular species, the regulatory approach often taken by state and federal governments, and frequently promoted by conservation organizations.

Further, if individual populations are to be protected adequately, they must be discovered and recognized while still viable. Ingram (1991) reported that a single specimen of the gastric-brooding frog (*Rheobatrachus silus)* was collected possibly as early as 1915, yet this species was not described until 1973. Now thought to be extinct, *Rheobatrachus silus* and its habitat might have received sufficient protection to ensure its survival had it been described 57 years earlier. This observation, plus the fact that even some of the most thoroughly explored parts of the earth (e.g., California) still hold undiscovered vertebrates (Greene and Losos 1988), suggests to us the need for expanded, rather than restricted, scientific collecting on a global basis.

What the counterproductive aspects of wildlife regulation demonstrates, of course, is that biologists, besides being the smallest among those groups interested in wildlife issues, are the least vocal and politically weakest group among logging, construction, and recreational interests, the leather industry, and animal importers and exporters. All of these other interests can afford legal aide (e.g., Pet Industry Joint Advisory Council) against disorganized, underinformed, and heavily bureaucratized international (e.g., CITES), federal (e.g., U.S. Fish and Wildlife Service [USFWS]), and state agencies. The result is that scientists, the segment of the "consuming" public that is the smallest and the least punitive to natural populations and one of the most important for rational habitat regulation, is also the most regulated. As an example of the resources of commercial compared with research interests, recently, in response to USFWS discussion of increased regulation of bird importation, the Pet Industry Joint Advisory Council was able to make a direct mailing to 1,000,000 households (Anon. 1992). This kind of effort is beyond the capability of any research organization.

Currently, the *documented* (Brautigam 1991; Busack 1974; W. King *in* Dodd 1986; Fitzgerald et al. 1991) commercial trade in amphibians and reptiles and their products is responsible for more than five times as much collecting *per year* than scientific collecting has accomplished in total for its *entire* history (data from Wake et al. 1975, plus estimates of non-U.S. collection holdings). This translates to scientific collecting being responsible for less than 1% of the annual regulated take of amphibians and reptiles. Further, the undocumented effects of human overpopulation and urban development are surely directly responsible for several orders of magnitude more deaths of amphibians and reptiles per year than either commercial or scientific collecting. Given that annual takes of amphibians and reptiles for commercial purposes are multiples of the number of specimens ever deposited in scientific collections, one must wonder if regulation of scientific collection is worth the administrative effort, particularly because few biologists have any interest in commercially valuable or truly endangered species. Although we agree that governments and international treaty organizations certainly have the right to regulate scientific collecting, it does seem that a more rational and expedient means could be found to insure the protection of species that are truly endangered rather than the unworkable and detrimental arrangement now in place. Further, if the failure of the United Nations Conference on Environment and Development (UNCED, Rio de Janeiro) to distiguish between scientific and commercial activities is any indication (Barton 1992), we likely can look forward to biodiversity research (i.e., systematics) being throttled by increased "biodiversity" legislation.

We expect that our comments presented here will have no effect on reducing habitat destruction where *Abronia* occur. We expect that we will live to see *A. mitchelli, A. fuscolabialis, A. fimbriata, A. anzuetoi, A. ornelasi, A. reidi, A. matudai, A. smithi, A. ochoterenai. A. leurolepis. A. montecristoi. A. bogerti,* and *A. chiszari* extinct, or found only in such small tracts as to be biologically nonviable. *Abronia montecristoi* may already be extinct inasmuch as its only known locality is one of the best known in Central America and no additional specimen has been collected in over 30 years[10]. Species inhabiting pine-oak woodlands (*A. aurita, A. lythrochila, A. deppii,* *A.* species "Guerrero," *A. gaiophantasma, A. graminea, A. mixteca, A. oaxacae,* and *A. taeniata*) may survive somewhat longer because of their more extensive habitats, even though this habitat is generally more accessible to humans. Nevertheless, we doubt seriously if any of these species (representing half of gerrhonotine anguid diversity) will survive the twenty-first century, with little possibility of any additional understanding of these animals because of legal restrictions that are part and parcel of these species' destruction. We also expect that our comments here will have the undesirable effect of making it more difficult to obtain collecting permits and export licenses from the pertinent countries, with no effective improvement of habitat conservation. After all, permit officials are human, and they do not enjoy being told that their policies and actions are counterproductive.

In short, most species of *Abronia* have already had their habitats severely disturbed and many species face extinction in our lifetimes. Our messages are: (l) protect their remaining habitats; (2) if this cannot be done effectively, let anyone have access to these organisms without permit—at least herpetoculturists will keep some of them going into the next century and they will be available for their nontrivial aesthetic value. If the effect of our statements is to make others press for legal restrictions in the taking of these animals, without serious protection of their habitats, then we can only lament that these people will have failed what is, in effect, a conservation biology IQ test. They will have put a new roof on a burning house.

FOOTNOTES

8. The plethora of overlapping U.S. state and federal wildlife laws, as well as visa policies, make it effectively impossible for Mexican nationals (as well as other non-U.S. citizens) to pursue collecting-based research in the United States.

9. Indeed, the state of California has opened state parks to off-road vehicles, providing that they remain on pre-existing trails, a restriction of dubious practical value.

10. The conclusion that this one specimen was the "last of its species," killed off by a scientific collector, would be almost certainly incorrect. El Salvador is well-known for its leadership in habitat destruction in Central America, an ongoing process well advanced in the region of the Hacienda Monte Cristo.

Anonymous Reviews: A Response To Wilson And McCranie

Wilson and McCranie (1993) have provided a generally good series of arguments for and against the anonymous peer review system, and both authors certainly are familiar enough with the system to qualify as knowledgeable critics. However, I was surprised to read several of their opinions, qualified as ". . . incendiary. . .," against the system, especially #2 which alleges that ". . . the editor and such a [vindictive] reviewer form a secret pact against the author."

While my publications experience is not as extensive as that of the authors, I have served as editor of various publications series, have had peer-reviewed manuscripts and grant proposals accepted, and have had some rejected. All of the editors it has been my good fortune to have known regarded their role not as part of any pact, but rather as a sort of interface between prospective authors and science. Some even went so far as to be a publication facilitator for novices or persons not fluent in English. Only once, for a co-authored funding proposal, have I received a rejection based in large part upon the snide commentary of a review committee member who implied a former association with my department, and whose identity I can guess. Happily, the work is proceeding with very adequate and diverse corporate support, privately solicited; sometimes success is the best revenge!

I can accept the thought that there are editors who are less conscientious about their role, and it seems that Wilson and McCranie (and persons with whom they discussed their stance) have encountered them. After all, editors, like other scientists, are human first and scientists/editors second, with all the room for ego abuse and lack of character that implies. While locating persons qualified and willing to serve as editors is not at all easy, neither is it impossible. Wilson and McCranie's criticisms, therefore, seem less appropriate to the system than to publishers who fail to replace dishonest or vindictive editors. I write this with the full realization that an author may pin an additional target on their derriere by making such an accusation against an editor, but not to speak perpetuates injustice—ultimately, we're entitled to all the rights and justice we're willing to stand up and defend. And several authors leveling such charges at an abusive editor would be, I feel, a considerable threat to the status of a journal and hence to that of its publisher.

Selection of reviewers and disposition of manuscripts after review together constitute a unique art form. It definitely is time consuming, but I am not at all sure it would be more expedient for authors and reviewers to correspond directly—in fact, I can easily imagine this process requiring **more** time than the present system! Direct correspondence might enhance cooperation, but I wonder at what point a cooperative known reviewer recommending constructive revisions would feel they ought to be a co-author? The editor's time per manuscript would be reduced, but this interface is a necessary part of editorial functioning.

For an anonymous reviewer to use the system to suppress competition is to my mind utterly contemptible, and is another damning indictment of the bucks-grabbing, overhead-generating nature of much research-mill science. An editor receiving one poor review and two good ones clearly needs to examine critically their choice of reviewers as well as the science involved, and failure to do so is editorial cowardice. But again, this is addressable through the publisher. Yes, there are economic decisions involved, and it's certainly possible to keep costly journal pages filled with papers which have received unanimously good reviews. But does this approach best serve science? I doubt it, and I expect Wilson and McCranie would agree. Reading Bob Jaeger's example of "academic revenge" saddened me—it really did—but it did not surprise me. If that's the logic with which tenure decisions routinely are made everywhere, then academia ought to

be about ready to implode. Why would a graduate student want to spend years developing in order to enter a system that routinely eats its young?

All of the editors interviewed by Wilson and McCranie seemed to agree (as do I) that the system is far from perfect, though it seems ultimately better than most alternatives. However, in the course of informal discussion with a mammalogy graduate student here (Mike Stokes, pers. comm.), I learned of an interesting and logical variant under discussion among KU's mammalogists (and, doubtless, elsewhere)—TOTALLY anonymous peer review, wherein the author is unknown to the reviewer, who remains anonymous to the author. This is easy for editors to implement, preserves the valuable parts of the present system, and reviewers who wish to identify themselves could continue to do so.

In conclusion, I thank Wilson and McCranie for initiating what I expect will be extensive, and I hope productive, discussion.

Cladism: The Great Delusion

"What a lovely day. Let's go and dig up some nodes."
—What palaeontologists don't say.

"Although the thrills of novel thoughts are to be nurtured, and all students to be introduced to them, there is an inherent danger that should be recognized, namely that a new concept be not mistaken through the thrill it bestows as a sort of 'divine revelation' of THE TRUTH."—H. M. Smith (1972)

—o0o—

Once again, traditional or evolutionary systematics has clashed with the "new science" of cladistics. Lazell (1992) has questioned the results of the application of the cladistic method to the classification of iguanine lizards (Frost and Etheridge 1989), and has been firmly rebuffed (Frost and Etheridge 1993).

But has he? Lazell may be a reactionary, but he is a very well-informed and thoughtful one; he deserved better than the patronizing "most people think as we do nowadays" condescension of Frost and Etheridge's reply. The truth is that cladism, while taking on the overtones of religious dogma at times amongst adherents who casually dismiss the wisdom of earlier great minds, is neither unanimously accepted amongst biologists, nor is it the "hard science" or "objective approach" that its supporters insist.

To the claim that cladism is the consensual philosophy of systematists of the nineties, I would observe that the many writings of S. J. Gould (a useful sample reprinted in Gould 1980) summarize some of the problems with the cladistic approach, and give examples of some of the implications of rigorous application of the rules of cladism (and I know of no cladist who *demands* less than rigorous application, though he may wisely stop short of *applying* such rigor). Gould has argued that not only does cladism force one to abandon such commonsense vernacular concepts as "fish," "zebras," or "apes," but it even prohibits one from considering dinosaurs to be reptiles unless one is also prepared to consider that birds are reptiles. Gould also notes that cladism relies upon inference and hypothesis, ignoring the fossil record almost entirely, not only in its details as regards the past history of particular groups, but also in its overall suggestions and hints as to how the evolutionary process has historically proceeded.

Foolish, too, would be the cladist who casually discounts the contributions to systematics and evolutionary biology of Ernst Mayr, who, in a recent updating of his 1969 work *Principles of Systematic Zoology* (Mayr and Ashlock 1991), went to some length (over sixty pages) to present a refutation of the cladistic philosophy, an approach that clearly disappointed an otherwise respectful cladist reviewer (de Queiroz 1992).

Other noteworthy doubters include the late A. d'A. Bellairs, probably the most prestigious British herpetologist of recent decades, who wrote in a book review (Bellairs 1989): "The emphasis is on characters of systematic interest rather than upon functional anatomy, a concomitant of the cladistic approach which will lead morphology into even greater disrepute than it currently 'enjoys' among other kinds of biologists. Furthermore, the work makes minimal concessions to the general herpetologist; for example, one looks in vain for any summary of the cladistic method or for a glossary of its wretched jargon. Elitism! One is just supposed to know, though one doubts if the subject is taught in any university in the United Kingdom."

More recently, the veteran herpetologist R. F. Laurent (1992) has presented a thoughtful essay on the shortcomings of cladism, noting some of the absurdities that can result from rigorous application of the Rules, and observing that any system that uses discontinuous categories (e.g., species) cannot accurately reflect true (presumably continuous) phylogeny. Other systems, he observed, are not truly phylogenetic either, but they do not pretend to be.

But I prefer not merely to appeal to inventories of prestigious nay-sayers and "magister dixit" arguments alone. I will try to categorize and analyze the problems with cladism in as objective a way as possible, keeping "ad hominem" arguments to the bare minimum (an ideal perhaps not achieved by Frost and Etheridge). Nonetheless, comments about practitioners of alternative approaches that can only be classified as "snide" do seem to be a stock-in-trade of cladists (note, e.g., the comments at the foot of page 99 in Farris 1990), so the reader is asked to forgive my occasional descent into a similar spirit in the arguments below.

The problems with cladism may be summarized as follows:
i) "Straw man" arguments that misrepresent the actual nature of competing approaches to systematics.
ii) The absence of new concepts behind the new and opaque jargon.
iii) Deliberate rejection of "hard" data, and incompatibility with the fossil record.
iv) The erroneous axiom that evolutionary history has been simple and overwhelmingly divergent (the principle of parsimony).
v) Subjectivity masquerading as objectivity throughout the discipline of cladistics, such subjectivity being evident in a) determination of character polarity; b) selection of sister groups; c) determination of which shared characters represent parallelism or convergence, and which represent evidence of common ancestry; d) arbitrary (or prejudicial) wording utilized to force complexly varying characters into "A or B" dichotomies.
vi) A concerted drive to assert with finality (or at least until the next hypothesis) that which one does not actually know.

These objections may be further elaborated as follows.
i) "Straw Man" arguments. Cladists (e.g., Frost and Etheridge) equate their procedure with the "recovery" of natural, phylogenetic groupings, and portray the primary opposing approach (evolutionary or traditional systematics) as defending absurdities such as the concept of the group that includes "my car and three geese." Yet traditional systematists have long sought to identify "natural" rather than "artificial" groups, primarily by examination of all aspects of the morphology (and fossil history) of a group

to identify parallelism. They have always acknowledged that convenient, "button-sorting" characters result in artificial keys, not natural ones. Thus, it was not cladists but traditional systematists who decided that a thylacine, despite appearances, was not a wolf. And while some early categories (e.g., the Pachydermata, for thick-skinned, huge, nearly hairless mammals like elephants, rhinos, and hippos) were clearly mistakes, such were abandoned long before cladists came on the scene.

It is in fact the traditional taxonomist of today, rather than the cladist, who uses judgment to note which characters are likely to be fundamental ones and which are recent, plastic, or adaptive ones, and who emphasizes the former and rejects the latter. A cladist, on the other hand, constrained by a ban on using "judgment" as to the quality of characters, and excluding most or all fossils on the usual ground that they don't reveal all the characters of interest, might easily end up with a "Pachydermata" clade, or some other grouping of species with certain superficial similarities.

ii) The language of cladistics is singularly inelegant. "Autapomorphy," "symplesiomorphy," "homoplasy," or "Wagner Neighborhood" are not attractive terms. Many sciences, of course, have to develop a body of technical terms to refer to concepts that have no simple name. But cladism, in introducing these new terms, is merely juggling and renaming old concepts (parallel evolution, convergence, shared derived characters, etc.) that have been familiar for over a century. The motivation may be either to give the veneer of a "new" science by introducing new words, or perhaps to impress the layman with the "difficult" new terminology—a philosophy summarized by the phrase "*omne ignotum pro magnifico*," which may be roughly translated "if you can't understand it, it's gotta be great." Neither of these is legitimate justification. The procedure recalls that of some of the "soft" social-study disciplines, preoccupied with recognition as "real" sciences, that have developed graceless and unnecessary terminology accordingly.

iii) In developing multi-character cladograms for complex groups of organisms, the only actual points of contact with past truth are those of the fossil record, with all of its deficiencies. But fossils are usually incomplete, often only fragmentary specimens, almost never with indications of soft parts. Since few of the cladists' preferred characters are likely to be evident, the first thing they do in developing a cladogram is to dump most or all of the fossils, on the pragmatic grounds that the characters of interest are not all detectable. For example, Pritchard and Trebbau (1984) listed and gave summary information on no fewer than 33 genera of pelomedusid turtles, of which only five had extant members. But Gaffney and Meylan (1988) included only nine genera (the five living forms, and four fossil ones) in their cladogram of the Pelomedusidae, without challenging the validity of the remaining 24 genera. Their chosen procedure gave them only one other choice—either dump most of the genera, or dump most of the characters. But in rejecting "inconvenient" or incomplete fossils, cladists also reject all contact with past reality, and plunge entirely into the field of speculation.

If cladistics were indeed a "hard" science, with predictive capability, it would be possible to foretell, from examination of extant taxa and application of the method, what one would find in the fossil record. Reading a cladogram in the approved fashion from the top down (and assuming the universally uncalibrated y-axis to represent "Time"), one may not be able to predict much about what may be discovered very early in the history of the group, but the most recent hypothesized bifurcation events should occasionally be subject to confirmation. The concept of the "node" and what it really is has been much discussed. Some consider a node to be a higher taxon; but a node does not include the taxa that derive from it, whereas a higher taxon includes both a node and its derived forms. Others (e.g., Brooks et al. 1984) consider a node to be a representation of a speciation event. But to include "events" and "taxa"—the intangible and the tangible—as comparable concepts in a scientific hypothesis raises difficulties of the apples-and-oranges type.

In the last analysis, a node, in order to have any standing in scientific discourse (i.e., be subject to at least potential confirmation by observing the real world) has to be a species, or at least an interbreeding population of organisms that may or not be conspecific with other, isolated populations, identified at that point in its evolution at which it first undergoes irrevocable branching into two lineages each destined to become distinct species. (They may ultimately become distinct at a higher taxonomic level). With this as a working definition, we would anticipate that fossilized "nodes" (the "missing links" of an earlier generation of evolutionists), or at least near-nodes, or arguable nodes, would be abundant. We would also expect that series of fossils from successive strata would document the morphological evolution of life, leading by progressive stages and regular dichotomous splitting to the taxa found today. Through the course of time, an early, modest diversity of generalized taxa would be seen to change progressively, bifurcate regularly into two (not three or more) branches, each of which would continue to change, and become more specialized as the complex modern fauna evolved.

This scenario is completely alien to what one actually finds. The real-world fossil record is characterized by such unpredicted findings as:

a) Fossil forms are often fully as specialized as living ones, and in many cases are more specialized (Gould 1980; Zangerl 1980). Forms that are clearly ancestral to living forms, unless essentially identical to them, are very scarce. Most fossil forms represent the ends of their respective evolutionary lineages, destined for extinction rather than alteration.

b) The predicted "nodes," or points of dichotomous bifurcation, are virtually absent from the fossil record. Even "near-nodes" are very scarce. And, curiously, cladistic palaeontologists do not even seem to be looking for them, or expect to find them. Somehow they lack faith in their own philosophy.

c) A typical taxon appears rather abruptly in the fossil record, and remains unchanged, or undergoes only inconsequential change, before becoming extinct several million years later (Gould 1980).

d) At very rare intervals, a spectrum of fundamentally new lineages appears essentially simultaneously, presumably in response to some drastic change in competition, or world climate or ecology. Such "adaptive radiation" may be dismissed as "unresolved polychotomies" by the cladists, but the important thing is, not to attempt to identify minuscule chronological separation between the origins of these diverse lineages, but to recognize that they were essentially (i.e., geologically) simultaneous.

Modern molecular systematists have tended to confirm what traditional systematists have known for a long time—that adaptive radiation is real. Thus, in the mtDNA sea turtle phylogeny presented by Bowen et al. (1993), the three branches of the Cheloniidae (Carretini, Chelonini, *Natator*) have essentially identical length, and apparently diverged soon after the K-T boundary. While the "molecular clock" may not tick at identical speed for all kinds of organisms, it clearly represents a useful tool for comparing divergence times within a group of related organisms. The cladist, on principle, cannot accept the statement that the three fundamental branches of modern cheloniid turtles diverged at essentially the same time; but the molecular data indicate that they did.

e) The greatest fundamental diversity (i.e., at the phylum level) appeared at the beginning of the fossil record (e.g., in the Cambrian Burgess Shale), not at the end of it (Gould 1989).

If one starts with the real data about the past, i.e., the fossils rather than the suppositions, one will come up with models such as the Punctuated Equilibrium model of evolution of Eldredge and Gould (1972), and will also show more than casual respect for

the concept of contingency—the purely accidental, unpredictable events of mutation, of selection, of chance, that happened to have occurred (but that would never have occurred again), that ultimately led to the modern fauna. One will find little evidence for the cladistic model. One will also inevitably form the view that speciation must most commonly occur in small populations, isolated by chance events in remote places where the selective forces are very different from those to which the species as a whole is subject. Most such populations will quickly go extinct; but a few, by dint of happy and appropriate mutations and not a little luck, will adapt to their new environment, and will speciate rapidly, *with the founder stock remaining unchanged*. We would have to use the same taxonomic designation for this founder stock before and after the splitoff occurred, since no difference can be detected. On the other hand, the offshoot stock, easily distinguished by many characters, should obviously have taxonomic recognition. But this is not acceptable under the Rules of Cladistics.

A sociological parallel would be that of a twenty-generation lineage of peasants. Let us assume that, somewhere about the tenth generation, forces of contingency conspired to educate the eighth daughter of one of the families so that she became an urban professional. She married into this class also, and all her descendants became urban professionals of one sort or another also. "Cladistics" would insist that, if generations 1–10 were all peasants, and subsequent generations except for the urban professionals were also undifferentiated peasants, then the offshoot lineage must be considered peasant also. Yet any observer would note that, if people look like yuppies, smell like yuppies, talk like yuppies, maybe, just maybe . . . .

As an example of the nomenclatorial, logical, and philosophical contortions forced upon cladists by some of their own arbitrary rules, note the "cure" proposed by de Queiroz and Gauthier (1992) for the cladistically unacceptable, although simple, statement "the Agamidae were ancestral to the Chamaeleonidae," a remark that does not elevate the blood pressure of the traditional systematist in any way.

The cladist may not disagree with the facts of the matter, but he cannot accept that the Agamidae, a successful, modern family, should have the same name both before and after it gave rise to the Chamaeleonidae. The proposed initial solution is to call the entire complex by the oldest available family name (i.e., Chamaeleonidae), thus utilizing a familiar name for an unfamiliar purpose, to designate both the agamids and the chamaeleons, and to leave nameless the two familar families recognized today. To this mess, de Queiroz and Gauthier resolve a further, even more drastic solution—the dumping of the entire Linnean system of nomenclature. Such iconoclasm is unlikely to appeal to anyone except highly theoretical cladists, in that most consider the Linnean system remarkably time-tested, having withstood the general acceptance of the theory of evolution, for example, without significant compromise. Those who do real, practical zoology, and need stable names to refer to the entities they study, will also not welcome total sacrifice of nomenclatorial stability on the altar of a theory that may well not survive the decade, let alone the centuries. Perhaps they will resort to standardized vernacular names, as have many ornithologists.

iv). In general, I have no problem with Occam's Razor (i.e., where several explanations of a phenomenon are possible, choose the simplest until it is disproved), nor with Dollo's Principle, which states that evolution does not reverse itself. But my visceral response to the Rule of Parsimony is to observe that nature is bountiful, not parsimonious. It is extremely unlikely that the actual sequence of past events can be portrayed by the *Hyphaene*[1] model; the *Salsola*[2] model is actually far more probable, in that evolution has demonstrably been extraordinarily complex, and species can be formed in many ways, including such bizarre means as tetraploidy, where interspecific hybrids become fertile with each other but not with either parental species (Wilson 1992). This results in the rejoining of divergent evolutionary branches into new, "composite" species, a phenomenon shown in no cladogram I have ever seen. As George Gaylord Simpson once said, "evolution does not work in straight lines, but the minds of some scientists do."

Furthermore, the assumptions underlying the Rule of Parsimony, i.e. that both evolutionary reversal and parallelism or convergence are so rare that the model that includes the least of these is necessarily the one of choice, may be hopelessly flawed. Dollo's Principle is not breached when individual characters reverse themselves, it only states that an entire organism cannot exactly duplicate an ancestor unless connected to that ancestor by a chain of identical generations. In the small, well-studied family Testudinidae, with about forty living species, parallelism and convergence—in shell shape, alternating octagonal and tetragonal neurals, radiating scute markings, gigantism, dwarfism, bifurcate gulars, male plastral concavity, thickened xiphiplastra, thickened or thinned epiplastra, enlarged forelimb scales, absence of bony cores in forelimb scales, elongate neck, single gular, conical vertebral scutes, absence of maxillary ridges, loss of nuchal scute, and many other characters (Loveridge and Williams 1957)—are so extensive that a cladogram simply collapses under the weight of the known homoplasies, let alone the reasonable suspicion of many more. Yet there is no reason to believe that homoplasies are atypically frequent in the Testudinidae—we simply have studied the present and past representatives of the group well enough to have identified many of them.

One might also consider zoogeographic reasonableless in deciding whether widely separated forms are likely to be congeneric, or whether the observed similarities are simply symplesiomorphic or homoplastic. Thus, Bour (1985) could find nothing to differentiate certain testudinid fossils from the Balearic Islands (western Mediterranean) from the sub-Recent Mascarene tortoises of the genus *Cylindraspis*; nor could Loveridge and Williams (1957) find definitive grounds for reversing Lydekker's (1889) allocation of the European Eocene *Emys comptoni* and Upper Miocene *Emys scutella* to the South African endemic tortoise genus *Homopus*. But in both cases "good zoogeographic judgment" (and not much else) would resist lumping such forms into single genera.

When a cladist generates a series of cladograms of which the "true" one is identified as such because it includes 23 rather than 25 cases of reversal or homoplasy, it must be realized that the real-world history of the group probably included hundreds or thousands of reversals, plesiomorphies, and homoplasies, most undiscovered or lost forever by the vagaries of the fossil record. So whether the gross simplification of that history that is offered by the cladogram identifies 23 or identifies 25 reversals or plesiomorphies is absolutely meaningless. There is, in reality, no valid way to choose between these two scenarios.

The Principle of Parsimony is a means of estimating the nature of something unseen by assuming that nothing unusual took place, that the sequence of events that is, statistically, the most probable can be hypothesized as that which actually occurred. A homely example will illustrate the absurdity of this process. Let us suppose you were to hold up an opaque sack containing a hundred live turtles, and asked a colleague to guess which species they were. The Rules of Parsimony would require that the colleague be familiar with all species of turtle and to know their relative abundance; they also require that he not be bound by any rules of common sense.

Even if you gave a helpful hint and showed that the first twenty turtles were, say, *Pseudemydura umbrina*, Parsimony would continue to insist that the 21st turtle was not this very rare form, and might constrain our cladist friend to guess that the remaining eighty turtles were all *Trachemys scripta*, on the grounds that any other turtle species was less abundant than *T. scripta*, and therefore less likely to be in the bag.

Clearly this is nonsense. Even if *Trachemys scripta* were the most abundant turtle in the world, the "guess" is unjustified, not just because the first 20 turned out to be something else (and that should tell us *something*, just as a coin giving heads every time after twenty tosses should tell us something), but also because representatives of this species certainly do not outnumber representatives of *all other species put together*. In other words, the category of all non-*scripta* turtles is more numerous, and thus more probable, than the category of *scripta* turtles alone. So also is the composite category of several different cladograms each with 25 plesiomorphies more probable than the single cladogram presented with 23 plesiomorphies.

Obviously there are times in life when one does not have enough information to make a useful guess to interpret a complex situation, and at such times scientists should decline to commit themselves. The traditional or evolutionary taxonomist is entirely within his rules to designate a family that contains several dozen genera, without any obligation to group them into subfamilies or suprageneric groups if he feels that the data are insufficient to guide such a grouping. On the other hand, a cladist working with the same group is obliged by *his* rules to illustrate the dichotomous branching that led to the extant array of genera, even if the data are subject to different interpretations (as they usually are). A great strength of the Linnean system is that it only *requires* barebones categories (Kingdom, Phylum, Class, Order, Family, Genus, Species) for a given organism or group, leaving other categories to the discretion of the reviewer. They can be filled in later, when the data become available, without doing violence to the established structure.

A further shortcoming of the methodology of cladism is that it does not differentiate between known, indisputable homoplasies; cases where homoplasy is possible; and cases where homoplasy is extremely improbable.

v). a). Determination of character polarity. Polarity (i.e., whether a character is primitive or derived) is a critical consideration, in that clades have to be justified by the sharing of *derived (i.e. apomorphic)* characters. It sounds simple, but it is often not so with real-life examples, yet cladism collapses if polarity cannot be determined unambiguously — too many characters entered without prior ordering will quickly generate logical chaos. It is important to remember that all organisms alive today, in the last analysis, have had the same amount of time to evolve, although some may *seem* to have made better use of their time than others. Thus, characters thought to be primitive may only seem so — they may appear similar to the characters shown by very early members of a lineage, but if they have been retained, they must either be selectively neutral, or (more likely) they are highly, even if subtly, adaptive to modern conditions. And if adaptive, and not connected to ancestral forms by a continuous fossil record, the possibility must be entertained that they disappeared and reformed.

I will take some examples from within my own field of specialty — turtles, the Order Chelonii. Let us say that we wish to determine whether the roofed skull of modern cheloniid sea turtles; or the broadly rounded carapace of modern *Lepidochelys*; or the presence of bones in the posterolateral margins of the leathery carapace of *Lissemys*, are primitive or derived. The fossil record does not help in that the continuity with the superficially similar characters of early ancestors (or near-ancestors) cannot be demonstrated.

Outgroup comparison can be attemped first. The obvious sister group for the cheloniids is *Dermochelys*, that happens also to have a roofed skull. But this is non-useful, in that the feature may be an adaptive one, common to all marine turtles, a shared derived condition, that conceivably formed independently more than once, of the lineage that includes both the dermochelyids and the cheloniids.

Bowen et al. (1992) used *Chelydra* as a sister group for the cheloniid/dermochelyid lineage. In this form the skull roof is highly emarginate. But if we had, with equal justification, selected the other living chelydrid genus, i.e. *Macrochelys*, we would have found a completely roofed skull. Going back further, we find that the earliest turtles and other anapsids had a complete skull roof, as do certain isolated living genera (*Pseudemydura*, *Platysternon*, *Peltocephalus*). But despite an unusually rich fossil record, and a group that has attracted many competent students, it remains unclear whether the fully-roofed condition of these turtles is a sporadically-retained primitive feature or a highly adaptive one associated with megacephaly, non-retractability, or something else.

As regards the wide carapace of *Lepidochelys*, both ontogenetic considerations (i.e., the wide, rounded shell of most hatchling turtles) and paleontological ones (i.e., the wide shell of certain early sea turtles such as *Toxochelys*) suggest that the discoidal form is primitive (Zangerl 1980). Yet those who have witnessed the unique, specialized nest-closing behavior of *Lepidochelys* can quickly become convinced that this feature is an advanced, specialized one associated with the "sand-thumping" post-ovipositional "dance" of these turtles. Or perhaps it is truly primitive but serendipitously pre-adapted for an important behavioral function of modern *Lepidochelys*.

Finally, in *Lissemys*, we find a trionychid genus in which homologs or analogs of some of the peripheral bones of other turtles are present, in a family of moderate diversity in which peripheral bones are otherwise lacking. The bones are sufficiently different in form and in number from normal chelonian peripherals as to raise significant question about their homology. Ecologically, the genus is unusual and apparently specialized within its family in that its preferred habitat is shallow, often temporary waters, and it has cutaneous plastral flaps that allow it to close its shell openings, presumably to retard dehydration under desiccating conditions. When tightly closed, the series of "peripheral" bones (which are not sutured to each other) are tightly folded or buckled on each side of the tail.

Accepting Meylan's (1987) proposal of *Carettochelys* as the sister-group to the trionychids, we find a continuous series of peripheral bones to be present in this genus. By this criterion, the "peripherals" of *Lissemys* are primitive. But careful analysis of the peripherals of *Carettochelys* raises questions as to *their* homology — there are only ten pairs (PCHP 3990 has only nine) instead of the usual eleven, and unlike the peripherals of almost all other turtles they do not become sutured with either the costal or the plastral bones even in old adults.

The homologous status of the peripherals of *Carettochelys* is thus also thrust into doubt, and this doubt then extends to the peripherals of *Lissemys*. The argument for primitive, "relictual" status of the latter is confounded also by the presence of a "preneural" bone in the anterior periphery of the carapace in this genus, a feature not found in non-trionychid turtles, and one that suggests neomorphic development rather than retention of primitive features. If such an autapomorphy can form at the front of the trionychid shell, then there is no reason why it could not form in the posterolateral region also. I recently picked up a large live *Lissemys scutata* in a restaurant in Beijing, and was struck by the extraordinary utility of this scrap of armor. When the head is retracted, the prenuchal bone bends downward, to meet the raised anterior plastral lobe. The head is thereby effectively and neatly helmeted—a potential life-saver, hardly a useless relic! On the other hand, Meylan (1987), in an exhaustive cladistic analysis of the trionychids, concluded that the peripheral bones of *Lissemys* were primitive. Primitive features may be adaptive, of course, but they cannot be consider derived. The polarity of the "peripheral" bones of *Lissemys* must remain an open question.

One might also ask how a conscientious cladist would determine character polarity in the rather small and nondescript Mexican emydid *Terrapene coahuila*. Noting the relatively vaulted shell and generalized (neither elephantine nor webbed) foot structure,

he would probably identify this species as a primitive form, perhaps close to the ancestral testudinid line, an aquatic species in process of becoming terrestrial, with the single specialization of a plastral hinge. But by bringing to bear paleontological, taxonomic, ecological, and genetic insights, one would recognize that this was an aquatic species in an otherwise terrestrial genus, which in turn was a member of a family of mostly aquatic species, which in turn were derived (through unclear pathways) from the presumably terrestrial earliest turtles. After just a few such reversals, the concept of "primitive" becomes subjective indeed, since the terrestriality of other members of the genus *Terrapene*, primitive when compared with *T. coahuila*, is clearly derived when compared with the Emydidae as a whole.

The optimistic cladist might have anticipated that his methodologies, elaborated just as molecular approaches to systematics were dawning, would be confirmed by these new techniques, but this has not proved to be the case. Thus, in the absolute sense, what may be considered to be the "primitive" state for a given character is ultimately reflected in a particular sequence of nucleotides within a DNA molecule. Each position within such a sequence is defined, not in subjective terms of "polarity," but simply as one of four possible states — A, C, G, or T. The cladist would be forced to accept majority rule as his criterion of polarity at the DNA level, since obviously no individual purine or pyrimidine could be considered "primitive," and this is clearly an unsatisfactory situation.

b). Polarity is often defined by comparing a morphological trait to the condition in a "sister group," or a wider "out-group" — ideally, a monotypic lineage that separated just below the base of the "clade" in question. Unfortunately, both selection and interpretation of sister groups is also fraught with subjectivity. Whether a usable sister group exists at all depends both upon whether such a group ever evolved, and whether it had the good fortune to survive to be studied. The cladistic process is itself utilized in identifying a sister-group, and this requires knowledge of character polarities; on the other hand, comparison with a sister-group is the main way of establishing character polarities in the first place. The process is thus tautological. Good judgment can be utilized to reduce the tautology, but in this nominally objective process, good judgment is not acceptable. Establishment of character polarity by comparison with a sister group is also highly vulnerable to misinterpretation through that persistent bugbear, homoplasy.

A parallel would be to attempt to determine what one's great-great-grandparents were like by looking for long-lost cousins. Not only has the "cousin" and his immediate forebears been living in the same changing world as oneself and thus making parallel life-style changes (does the fact that they all have televisions mean that one's ancestors must have had televisions?), but, as a parallel to the problems facing cladists, one may even be mistaken in accepting that the individual in question really is a relative! Moreover, the problem is further compounded if the "cousin" has many close relatives with whom he shares relatively few characteristics—the ideal "sister group" has to be monotypic, or nearly so, or the analysis becomes too complicated.

Finally, an example will illustrate that, even if one correctly identifies the polarity of a trait, one may nevertheless reach inappropriate phylogenetic conclusions. Many of the subspecies of the Galapagos tortoise (*Geochelone nigra*) show an unusual, shared condition, notably the saddlebacked shell, that correlates with many other characters (reduced size, relatively long limbs and neck, flared posterior carapace margin, white coloration of the head and throat, and various behavioral traits including sparring for dominance by raising the head as high as possible, and a tendency to flee rather than withdraw into the shell when threatened). Yet, although these characteristics certainly qualify as "synapomorphies," the conclusion that the saddlebacked tortoises form a "clade" may be incorrect. As Marlow and Patton (1981) have demonstrated by means of starch-gel electrophoresis techniques, the various isolated saddlebacked tortoise populations in the Galapagos archipelago almost certainly evolved independently, on their different islands, from dome-shelled ancestors. Zoogeographic considerations—the scattered appearance of saddlebacked tortoises in parts of the archipelago where arid conditions prevail (Pritchard 1979)—lend support to this hypothesis.

c) Character selection is critically important to the development of phylogenetic hypotheses. One can never include *all* characters, so the selection of characters to be used will inevitably have a subjective element. The cladist attempts to utilize numerous characters and in this way hopes to identify multiple synapomorphies. The evolutionary phylogeneticist, on the other hand, tries to identify those traits that seem especially conservative and that are not closely associated with function in order to establish fundamental points of evolutionary divergence. He is not fooled, for example, by the fact that both of the chelid turtle genera *Chelodina* and *Hydromedusa* have very long necks and flattened heads, or by the fact that *Terrapene* and *Cuora* both have a mid-plastral hinge, even though both characters are linked with a number of associated morphological and functional similarities. Gaffney (1977) established the taxon Infratribe Hydromedusad for *Chelodina* and *Hydromedusa*, but Pritchard (1984) argued that the characters of the head and neck that were used are obviously related to the feeding behavior or ecology of the animals. Rather, the evolutionary taxonomist would note that the anterior shell scutellation of the first two genera, a classic non-adaptive feature, is drastically different, and that the skull of *Chelodina* differs from that of *Hydromedusa* in having a uniquely single frontal bone and no parieto-squamosal arcade — subtly adaptive, perhaps, but not obviously so. And he would not be fooled by the superficial similarities of the two box turtle genera, in that the plastral scute formulae or the configurations of the pygal bone relative to the supracaudal scutes (conservative, probably non-adaptive features) are strikingly different.

Sometimes, numerous characters may, in fact, be expressions of a single, recent adaptive modification. A classic example of this is the effect that durophagy, even of an individual as opposed to a lineage, can have upon the skull of a turtle (see Stejneger, 1944). I once identified a complex spectrum of differences between the skulls and lower jaws of the two species of *Lepidochelys* (Pritchard, 1969); but apart from a few that could be attributed to the diurnal nesting habit of *L. kempi* (and associated with a smaller orbit), all were expressions of the durophagous habits of this species, manifest in many ways in the jaw musculature, tomial surfaces, and osteological features.

The cladist is drawn towards easy-to-describe, dichotomous characters (e.g. "maxillae in contact;" "frontal bone entering orbit;" "interpectoral seam longer than interfemoral seam.") But the functional significance of such characters may be that the skull, for reasons associated with the mode of feeding, has become narrower, and the orbits larger, perhaps to improve visual acuity. These adaptations may ultimately result in the maxillae achieving contact, or the frontal entering the orbit; but these are incidental by-products of the change in skull shape, and in themselves may be totally unimportant. Functionally, and phylogenetically, a close approach to the derived condition may be as significant as attainment of that condition. But, if the character is selected, not in a way to differentiate between forms that show the derived character and those that don't, but simply to differentiate between those that pass a threshold easily expressed in dichotomous terminology, then we will erroneously link taxa that do not show the character and those that do (but do not reach the threshhold), declaring them more closely related than those that almost reach and those that exceed the threshhold. Similarly, if the plastron changes shape for functional reasons, the key question may not be whether the interpectoral seam is actually longer than the interfemoral seam, but whether it is about as long (i.e., almost as

long or slightly longer), as opposed to 50% as long. In other words, the important development of relative lengthening of the anterior plastral lobe may be obscured if one's only criterion is whether a certain easily-defined threshhold has been passed.

In truth, characters can be selected, or described in carefully chosen words, to prove anything one wishes to prove, and this has often been done. A cynic might observe that cladists were intellectual PAUPers who not only use, but have, bad characters. If one wanted to argue that Galapagos and Mascarene tortoises, for example, formed a natural clade, one could identify the synapomorphies of gigantism, pigmentation, neck elongation, absent nuchal scute, foreshortened plastron without epiplastral thickening, sexual dimorphism greatly favoring males, enlarged anterior and posterior shell openings, absence of bony cores to the forelimb scales, tendency towards saddleback shell form, and certain other traits, and establish a "natural" clade—as did Darwin (1839), subconsciously or consciously, when he utilized the name *Testudo indica* for the Galapagos tortoises, until he was corrected (Darwin 1845). But no modern systematist considers these groups to be closely related.

Sometimes extensively varying characters—and the genuinely binary character is unquestionably exceptional—can only be forced into the "either/or" or binary configuration favored by cladists after considerable verbal gymnastics. As an example of the ease with which carefully defined binary characters can be used to confirm one's preconceptions, those who would argue that the chelid turtle genus *Phrynops* was close to the genera *Hydromedusa* and *Chelus* might use the character of "neural bones present" to distinguish this group from the remaining chelid genera, in which neurals are usually lacking. On the other hand, *Phrynops*, that often has rather few neurals, shifts into the camp with *Elseya*, *Emydura*, *Chelodina*, *Rheodytes*, *Pseudemydura*, *Platemys* and *Acanthochelys* if one uses the slightly different criterion of "neural bones reduced."

In this same vein, Meylan (1987) (a friend and valued sparring-partner in academic debate) may have been correct in suggesting that the trionychids, carettochelyids, and staurotypine turtles formed a natural clade, but the characters he utilized to demonstrate this are clearly riddled with homoplasies, if not downright bogus.

They include the shared presence of a foramen intermaxillaris; of an anterior plastral hinge; and of the presence of 18 or fewer peripheral bones. Yet examination of the first of these indicates that the irregular opening in the premaxillary area of large adult staurotypines (and, incidentally, in many large adult chelydrid specimens also) is a direct result of the deep upper rhampothecal invagination (that accommodates the long mandibular "hook") penetrating the nasal capsule and eroding through the bone in this area. The foramen in trionychids, that lack a mandibular hook, is entirely different in nature, and is present at all ontogenetic stages, although barely expressed in such forms as *Chitra*. It may or may not be homologous to the foramen in carettochelyids, in which there is a vast, cavernous connection between the palatal area and the nasal capsule that combines the internal nares with the foramen intermaxillaris, but Meylan is certainly incorrect in claiming that the function of this foramen in *Carettochelys* is to accommodate a symphyseal hook. As may be seen upon inspecting a skull and mandible of this form, the hook is short, and when the mouth is closed the point of the hook rests against the underside of the (single) premaxilla rather than penetrating the foramen.

It is true that all members of this "clade" have 20 or fewer peripherals, as opposed to the 22 typical of other turtles. But to suggest that the presence of 20 peripherals in *Staurotypus* and in *Carettochelys* and of none in trionychids is a manifestation of the same phenomenon is untenable. The peripherals of trionychids (as Meylan himself states) almost certainly disappeared by progressive and simultaneous reduction or retardation of all elements in the series, until finally they failed to appear altogether. This is different in kind from the reduction of a series of 22 fully-developed peripherals to 20 fully-developed ones.

As to the use of plastral kinesis as a synapomorphy, this seems to be the most homoplastic character of all in the Order Chelonii, with an astonishing array of independently-derived hinges, cutting across the front, the middle, and the rear of plastra; across genera, across species, across sexes; and in many cases absent in juveniles and developing with ontogeny. The diversity of hinging just amongst the living chelonians is reviewed by Pritchard (1993). Clearly kinesis is highly adaptive, and can develop extremely easily, and it has occurred so many times—apparently to accommodate better protection of the extremities, to facilitate oviposition, to facilitate visceral displacement during neck retraction, to facilitate respiration, to allow the turtle to gape threateningly with head retracted, or just to reduce the otherwise straitjacket effect of the shell, that the wonder is that *any* turtles remain (like the minds of cladists?) in an unhinged condition.

vi) The "zeal of the newly converted" shown by the younger cladists is not just superficial, and their self-congratulatory posturing ("now we have a Formula!") seems to me to stem from the psychological urgency of their obsession with becoming practitioners of a "hard science" rather than being "merely" historians. Furthermore, they have convinced themselves that the available evidence (even the minuscule fragment to which they have access) is indeed adequate to reconstruct the details of the phylogenetic history of life on earth, or at least to present a "most probable" hypothesis that is sufficiently credible as to be worth presenting. Yet, just as one is about to launch a reasoned critique of an inane cladogram, they withdraw it anyway and present a completely different one. I know of no other example where adherents to a particular scientific procedure show so much confidence in a methodology and so little in its results. They argue that convergent cladograms utilizing independent data sets will show progressive asymptotic approach to what really happened historically; yet they seem unembarrassed, for example, by the fact that the cladograms derived from, say, turtle skull characters may be grossly different from those derived from shell characters. One or the other must be wrong, and they do not indicate which.

Just as the majority of people in virtually every culture on earth profess to know the basically unknowable when it comes to the nature of the afterlife—a result of their intense *desire* to know rather than of their actual knowledge—so the cladist claims unshakable faith in his interpretation of the forelife, as a manifestation primarily of his overwhelming personal *need* to know what has gone before, or of his dissatisfaction with having so much morphological, or even genetic, biochemical, or paleontological information, available without knowing what it all means. Yet this process can lead to conclusions so ambiguous as to be absolutely useless. For example, Frost (1992) was able to develop 36 equally parsimonious trees for his data on the genus *Tropidurus*, and found no fewer than 26,588 "unrejected trees" for the same data set. The traditional systematist must be forgiven for wondering how systematics are advanced by such a plurality of interpretations.

The cladistic process—the drawing up of "Rules" for the creation of a finished product called a "cladogram"—is an extraordinarily legalistic and formalized process, whose revealed truth is entirely dependent upon the accuracy of the assumptions discussed above. Cladistic guidebooks such as that of Brooks et al. (1984) are disconcerting in that the style, in its dogmatic assertion of the "Rules," reads more like the Koran than a work of science. Take a couple of shaky axioms, mix with some slightly subjective, or uncritically selected, characters, run it all through the computer, and the approximations and inaccuracies of the raw material are compounded with the wild guesses that one would have preferred not to have had to make into a conclusion that bears no relationship to objective truth. But because it came out of a computer, it is often assumed by the naive to represent

unchallengable insight. (Wiser cladists simply dump computer output that seems wrong or goes against their grain, and try again until the results parallel their preconceptions! I have seen them do it.)

True, the computer program itself does nothing more than speed up what may otherwise take weeks or months to do by hand. It is the digestion, the massaging, the wholesale disposing, of the data that is necessary before the computer can handle it that is the problem. We live in an age characterized by a preoccupation with relegating difficult decisions or intellectual functions to machines. This may be harmless enough in some cases — the use of calculators, spell-check features, translation machines, and other modern conveniences does provide a useful result quickly, and the principal down-side is that they characterize (or cause?) a generation that not only cannot calculate, spell, or translate, but even expresses arrogance about its inability to do these things when machines are available.

But the use of computer programs to make judgmental decisions, whether they be on phylogenetic relationships between organisms or on one's suitability for a college education, is more sinister in that the product is likely to be less accurate than "informed human judgment" would have been, yet it is portrayed as superior. It represents an abdication of the responsibility of accumulating insight and knowledge in favor of employing a briefly-trained technician with a computer program and a small amount of standardized information forced (sometimes kicking and screaming) into "format." As O'Rourke (1993) said, "there's a difference between information and knowledge. It's the difference between Christy Turlington's phone number and Christy Turlington."

The preparation of a cladogram is nonetheless reminiscent of one of my own favorite pursuits in biology, that of the careful application of a set of arbitrary rules to the creation of a work of art known as a Synonymy. There is joy in the patient application of the Rules of Priority; the rejection of non-binomial forms; the careful identification of nomina nuda, nomina oblita, nomina rejecta, nomina conservanda, and others; the smoking-out of ever-older, more obscure, and more inaccurate works of the past; the delight in discovering a century-old typographical error; the terse and standardized abbreviation of the titles of ancient works, so rare that even few libraries have them, as if they were in everyone's household, on every coffee table; the triumphant declaration that the name everyone has used for the last century must now be challenged by a completely unfamilar earlier one, or even better, a new one; above all, the labored and loving cataloging of ancient mistakes, for that is what a synonymy is—a literal and chronological catalog of errors, with one tentative line of truth somewhere at the beginning, middle, or end of the structure. It is fun to formulate such things, and you need to know your group and its literature well to do it well, and it is certainly scholarship. But it is not really science, and the things it regards as important, whether they be old publications or old specimens, generate no special insight into objective biology. A holotype, for example, is only important because we have decided that it is important—it was probably a thoroughly undistinguished representative of its taxon, or (even worse) may even have been unrepresentative or atypical.

The saving grace of a synonymy is its lack of pretention. It undertakes only to follow the Rules and to research the literature in cataloging man's historical errors, his slow footsteps towards truth. Moreover, the true systematics scholar can use the Rules, not to change well-established names, but to find legitimate reasons why such names should be retained despite the challenge that more obscure or less-used names seem to present.

But a cladogram is more sinister—it claims insight into biological and historical reality, even convergence upon absolute truth, although the little problem of multiple equally parsimonious cladograms nixes any claim of actual representation of absolute truth. Yet it too is simply the product of the application of far-from-absolute rules. Strange that competing cladograms for the same groups of organisms, presented as showing progressive or asymptotic approach to objective reality, show so much more diversity than do even the most elaborate independent synonymies for the same species! Strange—or perhaps not so strange—is that those ultimate guardians of biodiversity and evolutionary evidence, the curators of natural history museums, are amongst the last to respond to cladistic hypotheses with enough conviction to cause them to relabel their stock, or even the doors of their cabinets. Perhaps it is just a manpower shortage, or perhaps experience has taught them to wait for the dust to settle, which inevitably happens literally, but rarely figuratively.

Yet cladism is not useless. It was invented by an entomologist (Hennig 1966), and in this field the subject species outnumber systematics researchers by hundreds or thousands to one. The fossil record of insects is minuscule. Many insects can fly, and thus have potentially unlimited powers of dispersal, so zoogeographical considerations and isolation are rarely helpful. In the face of an indigestible plethora of morphological data on contemporary species, and little else, one needs some formalized procedure for getting a "first cut" on how the incredible diversity of species may be related to each other. But application of cladistics to smaller, better studied groups with abundant fossil records is a different matter.

The parallel I would draw is as follows. To a beginning student breaking into a new area of study, the best approach may well be to get a printout of titles of relevant papers from an appropriate computer database, to "apply the formula," and see what it yields. He will learn much, and may well think he has learned everything. But he will not, overnight, gain the insight of a veteran in the field, who knows the literature (and knows which papers are worthwhile and which are not), has extensive unpublished contributions and "gray literature" in his files, and has a lifetime of experience, insight, and extraction of information and ideas from a huge variety of sources. He also has a keen, and humble, realization of how little he actually knows, of the shortcomings of his knowledge, and will say "I don't know" without hesitation when circumstances so demand. The former is in the position of the cladist, the latter in the position of the evolutionary or traditional systematist.

In conclusion, and in the (translated) words of Laurent (1992), "after the storm of pheneticism more or less 20 years ago, we are now faced with the hurricane of cladism." One can almost hear Laurent's *sotto voce* murmur "this too shall pass." The opaque language of cladism has become the *lingua franca*, the unchallenged dogma, of many systematists. Curiously, concepts not only of organic evolution by mutation, but also of punctuated equilibria, of cladograms, even of nodes and of the alternative interpretations of nodes either as species that are ancestral to two or more other species, or as genera or other higher taxa, were all anticipated as early as 1832, by C. S. Rafinesque in a letter to Dr. J. Torrey of New York; they did not originate with Darwin, Eldridge and Gould, or Hennig.*

So too, the objections I have raised to cladism are, for the most part, not new—many have been raised by such luminaries as Ernst Mayr, George Gaylord Simpson, and Stephen Jay Gould—but I fear that the contemporary peer pressure by the Cladistic Police is such that a great number of systematists are loath to point out the emperor's shortage of clothes. But I for one propose to remain unClad.

*Rafinesque on evolution: "The truth is that Species and perhaps Genera also, are forming in organized beings by gradual deviations of shapes, forms, and organs, taking place in the lapse of time... This is a part of the great universal law of PERPETUAL MUTABILITY in every thing."

Rafinesque on punctuated equilibria: "There is a tendency to deviations and mutations through plants and animals of gradual steps at remote irregular periods."

Rafinesque on nodes and cladograms: "My last work on botany . . . will be on . . . the reduction of our Flora from 8000 to 1200 or 1500 primitive Sp. with genealogical tables of the gradual deviations having formed one actual Sp. . . . It is not impossible to ascertain the primitive Sp. that have produced all the actual; many means exist to ascertain it: history, locality, abundance, etc."

Rafinesque on whether nodes are species or higher taxa: "Almost every genuine or primitive species will be found to constitute a peculiar genus."

HERPETOLOGICAL HUSBANDRY

Double Clutching Gould's Monitors (*Varanus gouldii*) And Gray's Monitors (*Varanus olivaceus*) At The Dallas Zoo

It is well established that the normal reproductive mode for a large number of squamates includes the production of multiple clutches of eggs per season, both in the wild (Fitch 1970; Iverson 1978; Lewke 1979) and in captivity (Brecke et al. 1976; Cohen 1978; Greatwood 1978; Naulleau 1973; Romer 1979; Tryon and Murphy 1982), but this capability has not been well documented in varanids (Auffenberg 1988). This report describes double egg clutches in *Varanus gouldii* and *V. olivaceus* at the Dallas Zoo.

Females are introduced to males for short periods during the captive reproductive season. At the Dallas Zoo, introductions for both species are usually initiated in late January, coinciding with lengthening photoperiods and artificial rain cycles (*V. olivaceus*). Specimens are introduced biweekly for durations of several days until courtship or copulation is observed. Pairs are then left together until breeding activity stops.

One *V. gouldii* (SVL=69 cm, tail length=97 cm), and one *V. olivaceus* (SVL=108 cm, TL=169 cm) produced two clutches per year for two consecutive years. The pair of *V. gouldii* copulated in December 1991 resulting in a fertile clutch on 1 April 1992. Forty-two days later a second clutch was deposited (infertile). Copulation in January 1993 resulted in a fertile clutch on 19 March 1993. The female copulated again on 2 May, and deposited a second fertile clutch on 16 July 1993.

TABLE 1. Interval in days between copulation and clutch dates for *Varanus gouldii* and *V. olivaceus* at the Dallas Zoo.

First copulation date	First clutch date (interval)	Second copulation date (interval)	Second clutch date (interval)
V. gouldii			
29 December	1 April (91)	— (—)	12 May (42)
11 January	19 March (67)	2 May (44)	16 July (84)
V. olivaceus			
17 February	16 May (88)	— (—)	4 July (49)
? March	24 May (?)	9 July (46)	7 October (136)

The pair of *V. olivaceus* was observed copulating in February 1992 with subsequent oviposition on 16 May 1992. A second clutch was deposited (infertile) 49 days later. In March of the following year a copulatory episode resulted in a fertile clutch on 24 May 1993. Breeding behavior was again observed on 9 July and resulted in a second clutch that was deposited on 7 October 1993. A summary of clutch intervals is presented in Table 1.

During 1992 and 1993 a total of 33 eggs (28 fertile) were produced by one female *V. gouldii*, of which 21 hatched. A total of 28 eggs (8 fertile) were laid by the female *V. olivaceus*, of which one hatched. See Tables 2 and 3 for mean egg dimensions and neonate measurements.

TABLE 2. Egg morphometrics of *Varanus gouldii* and *V. olivaceus*.

Mean Diameter (mm)	Mean Length (mm)	Mean Weight (g)	# of Eggs
V. gouldii			
Clutch #1			
33.7	59.8	38.6	8
Clutch #2 (infertile)			
6.9	19.0	11.3	5
Clutch #3			
34.5	55.0	39.4	10
Clutch #4			
33.9	58.0	39.0	10
V. olivaceus			
Clutch #1			
37.2	60.2	49.0	8
Clutch #2 (infertile)			
10.4	16.5	17.0	4
Clutch #3			
39.0	61.5	42.4	8
Clutch #4			
38.0	60.0	43.2	8

TABLE 3. Morphometrics for neonate *Varanus gouldii* and *V. olivaceus*.

Mean SVL (mm)	Mean Tail Length (mm)	Mean Weight (g)	# of Neonates
V. gouldii			
Clutch #1			
131.0	180.0	36.0	8
Clutch #2			
—	—	—	0
Clutch #3			
135.2	182.0	37.8	5
Clutch #4			
129.5	180.4	37.0	9
V. olivaceus			
Clutch #1			
142.0	170.0	41.0	1
Clutch #2

Features

- Catalogue of the potentially dangerous snakes of the World
- 864 living or fossil species and subspecies, assigned to 97 genera
- Original citations, type localities and updated ranges
- Exhaustive synonymies and present location of types
- Preface by Prof. Carl GANS
- Bibliography (over 2'100 references)
- Index (more than 10'600 terms)

Crotalidae

Porthidium COPE, 1871
Contributors : Dixon (see comment under *Bothrops*), Schätti, Smith

Porthidium Cope 1871b.
Type species : ***Bothrops nasutus*** Bocourt 1868 by subsequent designation (Dunn E.R. & Dunn M.T. 1940).
Atropos Rüppell 1845 *Atrops* Rüppell 1845 ***Atropus*** Müller J.W. 1865 ***Thanatophis*** Posada-Arango 1889b ***Thanatos*** Posada-Arango 1889b ***Lachesis*** Boulenger 1896a (part.) *Porthridium* Reyes et al. 1989 ***Atropoides*** Werman 1992 ***Cerrophidion*** Campbell & Lamar 1992
Range : central Mexico to Venezuela and Amazon basin of Peru and Bolivia
References : Campbell & Lamar (1989), modified by Schätti & Kramer 1993

Porthidium almawebi SCHAETTI & KRAMER, 1993
Porthidium almawebi Schätti & Kramer 1993.
Type locality : San Francisco de las Pampas (0°26'S, 78°57'W, Cotopaxi, alt. 1800 m).
Lachesis pulcher Boulenger 1896a (non ***Trigonocephalus pulcher*** Peters W. 1862c) ***Bothrops pulchra*** Amaral 1930c ***Bothrops pulcher*** Klemmer 1963 ***?Bothrops campbelli*** Freire-Lascano 1991
Range : Pacific slopes of Ecuador and Pacific lowlands of Colombia
Type : Muséum d'Histoire naturelle de Genève, 2248.12 (holotype)
Notes : 1) Campbell & Lamar (1989 and 1992) [illegible] under the name *Bothrops*

Ectopia Cordis In Hatchling *Alligator mississippiensis*

Ectopia cordis is an unusual developmental anomaly in which the heart protrudes through a congenital cleft in the ventral body wall (Cotran et al. 1989). We have noted this abnormality extremely rarely in hatchling American alligators *Alligator mississippiensis*, which either died during incubation or were likely to be non-viable at the time of hatching. During the alligator hatching season in August 1991 however, we observed several cases of this unusual anomaly in hatchling alligators which initially appeared to be otherwise strong and vigorous. We attempted to salvage these alligators and herein describe their courses.

In June 1991, approximately 25,000 alligator eggs were collected from marshes in southwest Louisiana and from Rockefeller Wildlife Refuge in Grand Chenier, Louisiana. The eggs were collected and incubated as previously described (Joanen and McNease 1977, 1987, 1989). Incubation temperatures were checked daily with bulb thermometers, and water and incubator temperatures monitored continuously with Taylor recorders. The average temperature was 31–32°C. The first clutch of eggs hatched on 6 August 1991 and the peak of hatching was 19 August 1991.

Alligator "A" hatched on 16 August 1991 and a small ventral body wall defect with protruding heart and pericardium was noted immediately (Fig. 1). The heart was beating in a regular fashion and the hatchling was quite vigorous—able to support its own weight, swim, and locomote normally. It was separated from other alligators in a plastic storage box tilted to provide an area of clean water and a dry resting area. The container was left in the incubator at 31–32°C to avoid any sudden change in temperature. Attempts were made to keep the container and water as clean as possible, with minimal disturbance to the hatchling. On 17 August 1991 the hatchling measured 25.0 cm in length, and weighed 50.6 g. By the morning of 18 August 1991 the alligator was much less vigorous, with less spontaneous movement, and continued to deteriorate throughout the day. The alligator was found dead the next morning. At necropsy a pericardial exudate was found, and the lungs appeared slightly atrophic and congested. The liver appeared unusually fatty and residual yolk mass was 7.7 g. Internal examination of the gonads showed the animal was a female.

Alligator "B" hatched on 18 August 1991 and was 25.5 cm in length, and weighed 46.4 g. The hatchling was treated and maintained in the same manner as alligator "A." It also appeared normal and healthy except for the ectopia cordis. However, the hatchling gradually deteriorated and on 19 August was becoming lethargic, had little spontaneous movement, and showed development of a thin pericardial film. The hatchling was found dead on 21 August 1991, though it had probably died on 20 August 1991. On necropsy what appeared to be a heavy pericardial fibrinous exudate was noted, though histopathology was not available. The lungs were slightly congested and atrophic. The liver and other abdominal organs appeared normal, and the residual yolk mass was 6.1 g. Internal and external examination showed the hatchling was a female.

Alligator "C" hatched on 23 August 1991. The hatchling was 25.5 cm long and weighed 49.2 g on 25 August. The hatchling was reasonably strong; it was able to support its weight, locomote, and swim normally. We believed that the development of the pericardial film may have compromised cardiac function or led to the development of pericarditis in the two hatchlings already described, thus we mechanically stripped off the gray pericardial material exudate in alligator "C" and the area was cleansed with betadine, an antimicrobial solution.

On 26 August the alligator appeared somewhat weaker. The pericardial material had reaccumulated, and was stripped and the area cleaned again. Despite these measures, the animal was found dead on 27 August. At necropsy the gray pericardial film was again noted, but the lungs were normal. The liver was moderately fatty, and the residual yolk mass was 8.3 g. Internal and external examination again revealed the hatchling was female. No attempts were made to feed alligators A, B, or C as we generally do not initiate feeding until hatchlings are three to four days old.

Three other alligators were hatched with ectopia cordis and multiple other defects. No attempts were made to sustain life, the animals were immediately euthanised.

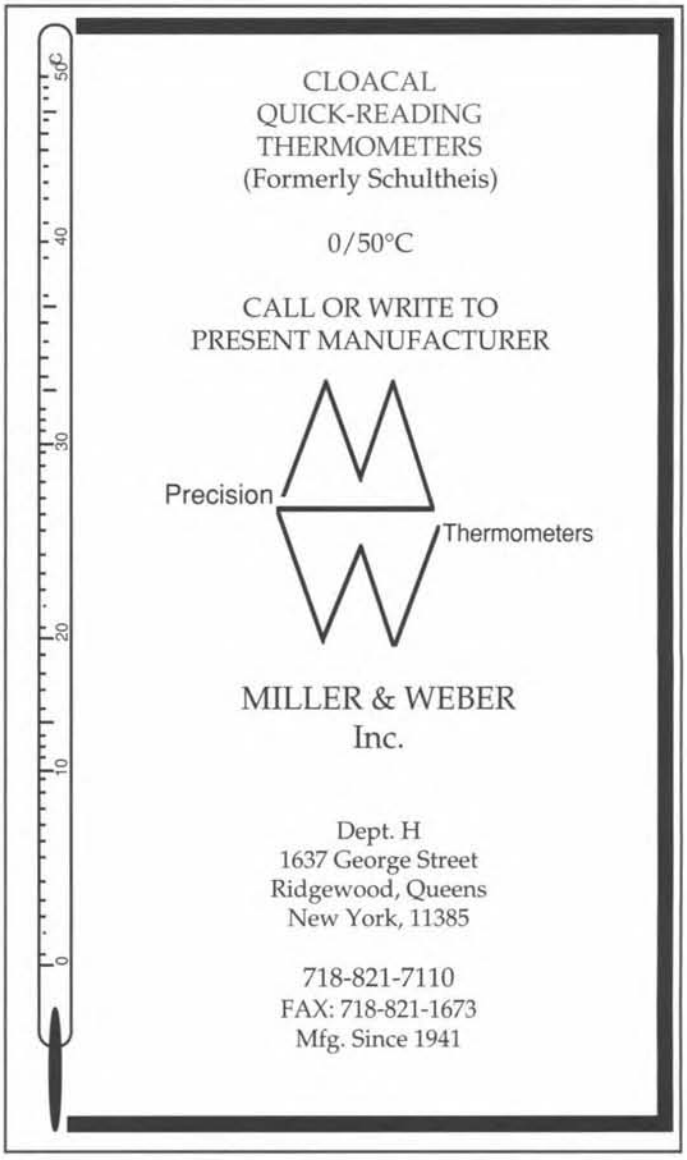

FIG. 1. Hatchling *Alligator mississippiensis* with ectopia cordis.

Alligator "D" had a large ventral defect with protrusion of the beating heart, stomach, fat body, and residual yolk. The weight was 45.9 g after formalin fixation. Alligator "E" also had a massive ventral cleft with herniation of the entire heart, and parts of the stomach, gall bladder, spleen, liver, and intestine. Other abnormalities included spinal scoliosis, hypopigmentation, and absence of the mandible. The weight was only 24.96 grams after formalin fixation. Alligator "F" had a massive yolk herniation in association with the cardiac defect and craniofacial abnormalities, including bilateral anophthalmia, and maxillary and mandibular malformation. The length was 15.5 cm and weight 28.1 g. Residual yolk mass was 11.0 g. A thick black material covered the exposed heart. The sex of alligator "F" could not be determined due to tissue necrosis; alligators "D" and "E" were females by cloacal examination of the clitoropenis.

Many congenital abnormalities have been described in reptiles (Bellairs 1981; Ewert 1979) and reptilian developmental anomalies were recently reviewed (Frye 1991). Ferguson (1985) reviewed developmental abnormalities of crocodilians including thoracoabdominal herniation, and the comparative anatomy of the crocodilian heart has been studied in detail (Webb 1979). We are not aware of previous descriptions of living alligators with ectopia cordis. A similar condition has been described previously in an eastern hog-nosed snake, *Heterodon platyrhinos* (Frye 1991). We are aware of only one other case of ectopia cordis in another crocodilian; Dr. G. Webb (pers. comm.) noted one case in approximately 31,000 *Crocodylus porosus* hatchlings examined; the animal was believed to be non-viable and was euthanised.

The pathogenesis of most reptilian developmental abnormalities is unknown; abnormally high or low incubation temperatures have been suggested as possible factors (Ferguson 1985; Frye 1991). Webb and Cooper-Preston (1989) noted more abnormal embryos developed at high incubation temperatures in *C. porosus*. It is of interest that all alligators in our series able to be sexed were females, as most crocodilians are known to have temperature dependent sex determination. We are unaware of any abnormal high/low temperatures incurred during incubation of the affected alligators, and temperature recordings were continuous on 24 h recorders.

The alligators in our study were probably too small to attempt surgical repair of the ventral defect. Further study is warranted as to the pathogenesis of reptilian developmental anomalies, particularly in the interest of commercial and conservation crocodilian farming and ranching programs, which incubate and hatch thousands of crocodilians worldwide annually.

Observations Of Growth After Injury In The Slider Turtle, *Trachemys scripta elegans*

An abnormally shaped red-eared slider (*Trachemys scripta elegans*) was collected 31 July 1991 in Slate Creek, 3.2 km S of Wellington, Sumner Co., Kansas, T32S, R1W, Sec. 26. The specimen had a rubber "O" ring around its carapace and plastron which had restricted normal growth, and had formed this specimen into an hourglass shape (Fig. 1). Recovery from this type of induced deformity has not been reported previously. The purpose of this study was to determine whether the turtle's shell would return to normal shape by natural means once the "O" ring was removed. Additionally, the effect of this constriction on the turtle's skeletal development was investigated.

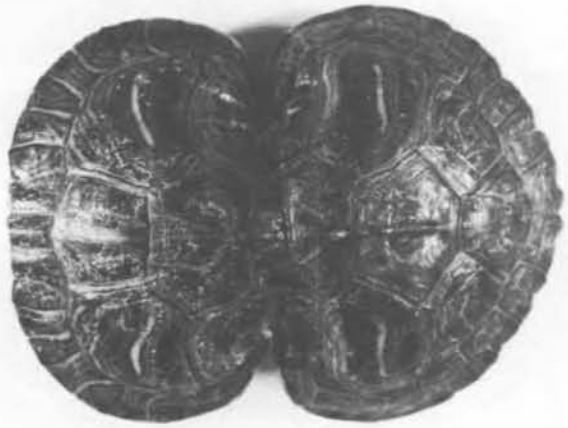

FIG. 1. Photograph of observed specimen after "O" ring was removed.

The study was carried out between November 1991 and October 1992. Age of this male specimen, determined by counting growth annuli on the carapace (Zug 1991), was seven years at the beginning of the investigation. The turtle was kept in captivity, and food, temperature, and light were maintained as near to normal conditions as possible. The turtle was not exposed to a winter cooldown however, as it was believed this would hamper potential for growth during the short time period of this study. Air temperature was held between 20 and 25°C, with a basking site of 32–38°C. Infrared heat lamps were used in combination with fluorescent and filtered natural lighting. No dietary supplements or other artificial growth enhancements were used. Food was varied to keep with the omnivorous habits of *T. scripta* (Parmenter and Avery 1990). Diet included live and frozen native fish, live goldfish, invertebrates, plant matter, and a carrion substitute (stewing beef).

For the first 28 days, weekly measurements were made by ruler, as follows: carapace length (CL), carapace total width front (CTWF), carapace total width rear (CTWR), restricted carapace width (RCW), and plastron length (PL) (Fig. 2). Subsequent measurements were made on a monthly basis. Two radiographs were taken on 6 November 1991, a lateral view and a superior view through the dorsal surface. Another set of radiographs was taken on 14 October 1992 using the same technique to allow comparison and to check for growth in the specimen. Body depth measurements were made from the radiographs from top of carapace to bottom of plastron for the anterior (ABD), posterior (PBD), and constricted (CBD) regions. Other measurements of skeletal structure were length of right femur, distance between pelvic and shoulder joints along the midline, and width of skull.

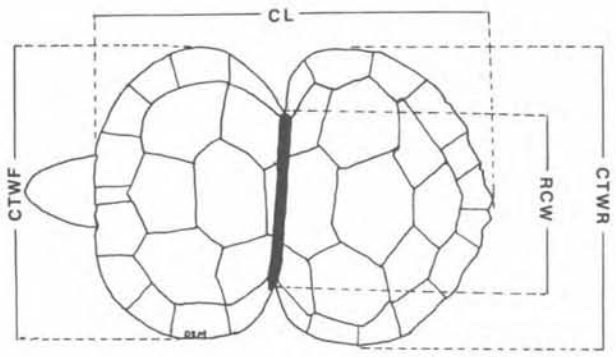

FIG. 2. Regions measured on *Trachemys scripta elegans* specimen.

During the initial 28-day period, no measurable growth occurred. When final measurements were taken on 14 October 1992 (see below), some changes had occurred, but no differences were noted in measurements of the right femur, distance between shoulder and pelvic joint along midline, width of skull, or CTFW. Measurements (in mm) taken 6 November 1991 and 14 October 1992 (343-day interval) are as follows: CL 121/129, CTWR 94/96, RCW 41.5/43, PL 117/122, ARD 45/47, PBD 44.5/48, CBD 33.5/38.

Very little growth occurred over the period of 343 days in which observations were made, nor did the carapace and plastron return to normal shape. In a study of two *T. scripta* populations, Cagle (1946) reported that adult male turtles had an average increase of 2.7 mm PL per 100 days of growing season. The specimen in this study had an average increase of 1.5 mm PL per 100 days. Observations showed that the shell deformity did not seem to inhibit food consumption, digestion, or motility. Radiographs of this specimen showed no indication of internal structural deformity other than a slightly depressed spinal cord at the point of constriction.

Dunham and Gibbons (1990) monitored growth of three populations of known age specimens of *T. scripta*. The average PL for 10-year-old males was 162.6 mm and the average for five-year-old males was 143.6 mm. Based on their results, the average size of an eight-year-old male would be approximately 155 mm PL. This can be compared with 122 mm PL of the study specimen.

One possible explanation for slow growth rate in this specimen is that growth was limited during the period of observation due to captive maintenance. Individuals kept in captivity often do not attain the size of specimens in the wild.

Another possibility is that the depressed spinal cord shown in the radiographs influenced growth rate by affecting the central nervous system (CNS). This prospect is less likely because such damage would be indicated by sensory and motor abnormalities in the rear limbs, none of which was observed. Slow growth of the shell around the "O" ring would cause the spinal cord to grow with the shape of the shell, thus inducing a re-routing of the CNS rather than a directly interfering injury.

A third explanation for the slow growth could be that the specimen was similar to that of 29% of males (100–110 mm PLs) in Cagle's (1946) study which showed only slight growth during his investigation. It may be that this specimen had a naturally lower than average growth rate. Further, Legler (1960) suggested that growth may temporarily cease in *Terrapene ornata* following injury. Thus, constriction of this turtle's shell could have slowed growth rate of this individual.

Acknowledgments.—I thank David Edds for his assistance, helpful comments, and criticisms throughout this project, and J. E. Simmons for encouragement, comments, discussion, and for graciously providing requested material. I also thank P. Shipman and T. Lindskog for making this turtle available for study. This specimen was collected during research on aquatic turtle assemblages funded by a grant from the Emporia State University Faculty Research and Creativity Committee and by a Chickadee Checkoff grant from Kansas Department of Wildlife and Parks' Nongame Wildlife Improvement Fund.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in volume 25, number 1.

ANURA

BUFO BOREAS (Western Toad). **PREDATION.** *Bufo boreas* is prey of *Corvus corax* (common raven) in Oregon, USA (Olson 1989. Copeia 1989(2):391–397). Based on Olson's description of the carcass remains, Corn (1993. Herpetol. Rev. 24(2):57) reported finding similar remains of *B. boreas* in Colorado, USA and suggested predation by the same species. This note documents predation on *B. boreas* by *Corvus brachyrhynchos* (American crow).

FIG. 1. *Bufo boreas* carcass after feeding by *Corvus brachyrhynchos*

On 13 and 14 April 1991, I observed two *C. brachyrhynchos* pecking at live toads at the water edge of a 0.05 ha pond located in Sec. 32, T4N, R4E, Boise Co., Idaho, USA (elevation 987 m). On 14 April binoculars were used. One crow dragged an adult *B. boreas* from the water. It then forcefully pecked the toad repeatedly. Following series of pecks, the crow wiped its beak on the ground. The crow repeatedly turned the toad on its back. Initially, the toad would right itself. After a few more forceful pecks, the toad would be overturned again. When the toad did not right itself, pecking commenced on the underside. Feeding began when the crow had pecked a hole through the toad's venter. Entrails were pulled out

FIG. 2. View of the underside of a *B. boreas* (as it was found when feeding by *C. brachyrhynchos* was interrupted) revealing puncture wounds and an opening made for feeding.

and consumed. Periodically, the second crow would feed on the toad. After eating the entrails, the crows fed on muscle tissue of the body and limbs through the hole, making it progressively larger. The remains of the toad carcass appeared to have been turned inside out and dismembered, with much of the skin intact (Fig. 1). Two other toad carcasses were found at the site and the remains were similar. Oviducal egg masses of a female were not consumed. On 7 April 1993, two crows again fed on an adult *B. boreas* at the same pond. They were disturbed before consuming much of the toad. The toad carcass revealed early feeding signs, including beak puncture marks (Fig. 2). These observations suggest that *C. brachyrhynchos* may also be an important predator of adult *B. boreas*.

Submitted by **DONALD R. BROTHERS**, HC 33, Box 1176, Boise, Idaho 83706, USA.

BUFO MARINUS (Marine Toad). **FEEDING BEHAVIOR.** Since introduction on Guam, Mariana Islands in 1937 (Chernin 1979. unpubl. MS thesis, Univ. Guam, 56 pp.), populations have reached substantial densities and are currently viewed as a pest species (McCoid 1993. Herpetol. Rev. 24:16–17). Marine toads are ubiquitous on Guam and can reach mean population densities as high as 225 toads/ha at certain sites (Chernin, *op. cit.*). Opportunism in feeding of extralimital urban dwelling *B. marinus* has been documented (Alexander 1965. Herpetologica 20:255–259; Tyler 1989. Australian Frogs. Viking O'Neill Publ., Ringwood, Victoria, 220 pp.). Alexander (*op. cit.*) observed feeding on kitchen scraps and canned dog/cat food in Florida and Tyler (*op. cit.*) observed feeding on dog food in bowls in Australia. To these extralimital feeding events, I add observations from Guam. Over a several month period in 1990, while a dog was being raised on Division of Aquatic and Wildlife Resources (DAWR) property, a number of *B. marinus* would gather daily, immediately after dried dog food was poured into a bowl. A group of at least six (sex unknown) toads (estimated SVL 7–10 cm SVL) would gather at the bowl after the food was poured, generally beating the dog to the food. Upon

arrival of the dog, toads would withdraw < 1 m and resume feeding only after the dog had departed. Toads would space themselves equally around the bowl and feed on the dried dog food by flicking their tongues into the food and drawing a piece into their mouths. This spacing has been observed in a native population exploiting a shared food source and was termed a "snap zone" (Zug and Zug 1979. Smithson. Contrib. Zool. 284, 58 pp.). Presumably, by equal spacing, overlapping snap zones would be minimized and toads would be able to share a resource area (Zug and Zug, *op. cit.*). Previous field and laboratory studies of snap zones used animate objects as targets; observations presented here suggest the use of snap zones with inanimate prey.

Zug and Zug (*op. cit.*) suggested that *B. marinus* learn to eat stationary food. An additional observation on Guam also indicates that toads attempt to ingest unusual inanimate prey. During an outdoor barbeque at which revelers casually discarded bones on the lawn, at least one *B. marinus* was photographed hopping off into the underbrush with a pork rib bone protruding from its mouth.

I thank Robert A. Anderson (DAWR) for supplying photographs of the pork rib incident. Rebecca Hensley reviewed a draft of the manuscript. Portions of this study were supported by the Endangered Species Conservation Program, Project E4.

Submitted by **MICHAEL JAMES MCCOID,** Division of Aquatic and Wildlife Resources, P. O. Box 2950, Agana, Guam 96910, USA. Present address: Caesar Kleberg Wildlife Research Institute, Texas A&M–Kingsville, Kingsville, Texas, 78363, USA.

HYLA MINUTA (NCN). **PREDATION.** Metamorphosing anurans are common prey for a variety of vertebrate and invertebrate predators (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York. 670 pp.). Although aquatic invertebrates represent important predators for some hylid tadpoles, there are few reports of predation on adults (Hinshaw and Sullivan 1990. J. Herpetol. 24:196–197). Herein, we report predation by a spider and a water bug of a metamorphosing and an adult (respectively) neotropical hylid frog, *Hyla minuta.*

On 1 August 1992 at 2015 h (air temperature 18°C), we found an adult male *H. minuta* (21.8 mm SVL) on the edge of a temporary pond in São Mateus (18°42'S; 39°1'W), State of Espírito Santo, Brazil. that was being eaten by the water bug *Lethocerus delpontei* (58.9 mm body length). The water bug held the treefrog by the back with its raptorial forelimbs. Males of *H. minuta* usually call from branches of emergent vegetation or the ground close to the water. These calling sites expose the treefogs to invertebrate predators.

On 10 February 1993 at 2200 h (air temperature 19.5°C, water temperature 22°C) in a permanent pond at Ribeirão Branco (24°13'S; 48°46'W). State of São Paulo, Brazil, there was a large number of newly metamorphosed *H. minuta* (mean TL = 24.9 mm total length, N = 17) on vegetation near the water. We found a spider *Dolomedes* sp. (15.3 mm cephalothorax and abdomen length), perched on a rush 50 cm above the water, eating a metamorph *H. minuta.* The water bug and the spider are preserved in the Museu de História Natural (ZUEC. without numbers), UNICAMP.

We thank A. S. Abe, C. F. B. Haddad, and A. d'Heursel for suggestions on text, J. Vasconcellos-Neto and E. Gianotti for identifications of the spider and the water bug, respectively, to the CAPES and CNPq, to the ARACRUZ CELULOSE S. A. (Projeto Sapé do Norte I) and FAPESP for financial support (C. F. B. Haddad, proc. 92/0631–2) .

LEPTODACTYLUS OCELLATUS (Rana criolla). **PREDATION.** Reviews of the evolution of parental care in frogs cite *Leptodactylus ocellatus* as one of a few documented cases where a female guards a school of tadpoles. Vaz-Ferreira and Gehrau (1975. Physis 34:1–14) speculated that females protect the tadpoles from avian predators. However, natural avian predation on tadpoles has never been confirmed.

On 19 February 1993, at 0925 h we observed natural predation by six great kiskadees (*Pithangus sulphuratus*) on a school of unattended *L. ocellatus* tadpoles. The tadpoles were in a dense aggregation partially hidden by vegetation in the center of a 4 x 2.5 m shallow (< 30 cm deep) temporary pool near Arroyo del Toro Muerto in Flor Serrana, Province of Cordoba, Argentina.

The birds landed either on a small island in the pond or perched on a fallen tree near edge of the pond and flew to the aggregation, captured tadpoles and returned to the tree or island where they ingested them. Although the individuals alternated between capturing and feeding on the tadpoles, two or three different birds fed constantly on tadpoles.

We found several dead tadpoles in premetamorphic stages 40 to 41 (Gosner 1960. Herpetologica 16:183–190) ranging from 41.2 to 48.3 mm in total length. Remains of numerous tadpoles' intestines indicated that the kiskadees were feeding.

Leptodactylus ocellatus tadpoles form conspicuous, tightlypacked aggregations that move constantly, making the entire school noticeable to predators requiring visual cues. Such aggregations could be related to the distastefulness of the individuals (Wassersug 1973. *In* J. L. Vial (ed.), Evolutionary Biology of the Anurans, pp 273-297. Univ. Missouri Press, Columbia). However the present observation does not support this hypothesis.

RANA PRETIOSA (Spotted Frog). **REPRODUCTION.** On 23 March 1993 in the Bishop Springs Marsh complex, Snake Valley, Millard County, Utah, a 49 mm snout-vent length (SVL) male spotted frog (*Rana pretiosa*) and a 52 mm SVL female leopard frog (*R. pipiens*) were observed in amplexus. The frogs were observed in an 8 m x 14 m pool within a spring-fed marsh complex. The water temperature was 19.5°C and the air temperature was 27°C. A second *R. pipiens* (23 mm SVL) and 23 *R. pretiosa* egg masses were also observed nearby. Egg masses of *R. pretiosa* had some eggs exposed above the water surface, were unattached to vegetation (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co. Boston, Massachusetts. 336 pp.), and consisted of at least twice the gelatinous material as those of *R. pipiens*. Egg masses of *R. pipiens* were deposited in dense, firm clusters, attached to vegetation, and did not float above the water surface. We found no previous reports of interbreeding between *R. pretiosa* and *R. pipiens*, but *R. pretiosa* hybridizes with *R. cascadae* in Oregon (Green 1985. Herpetologica 41:262–267) and with other ranid frogs in the laboratory (Dumas 1966. Copeia 1966:60–74; Haertel and Storm 1970. Herpetologica 26:436–446). An evaluation of the magnitude and significance of interbreeding between these two species in Snake Valley requires further study. We thank P. S. Corn and P. Hovingh for reviewing this note.

RANA UTRICULARIA (Southern Leopard Frog). **ROAD MORTALITY**. Investigators conducting surveys of road-killed vertebrates generally encounter few amphibians (e.g., Christoffer 1991. Florida Sci. 54:65–68; McClure 1951. J. Wildl. Manag. 15:410–420; Scott 1938. Amer. Midl. Nat. 20:527–539). This is undoubtedly due to the small, relatively fragile body of amphibians which is easily overlooked, readily obliterated by vehicular traffic, and quickly consumed by predators. Furthermore, road-kill surveys are typically performed diurnally, a time of reduced amphibian activity (Pechmann and Semlitsch 1986. Can. J. Zool. 64:1116–1120), as well as from a moving vehicle, a perspective from which amphibians are often overlooked (pers. obs.).

This paper details anectodal observations of road-killed *Rana utricularia* metamorphs adjacent to a semi-permanent pond approximately 2.7 km N of Blountstown, Calhoun County, Florida (TlN, R8W, Sec. 20) on 19 April 1991. The 1.2 ha pond is within a developing subdivision. Approximately one half of the pond is surrounded by an open field dominated by weedy graminoids, the other half by a stand of mature *Quercus virginiana* (live oak), *Q. nigra* (water oak), and *Nyssa sylvatica* (black gum). Observations were made along 0.3 km of a 5 m wide, dead-end, clay-sand road which passes within 8–20 m of the east-southeast end of the pond.

Mortality of emigrating *Rana utricularia* from vehicular traffic was assessed by slowly walking and scanning the road surface with the aid of a headlamp between 2115 and 2145 h. The road was wet from a late afternoon thunderstorm. All living and freshly-killed metamorphs encountered were collected and counted. Live metamorphs were released. The mean wet-mass body weight of eight intact dead metamorphs was 4.65 g (measured with a Pesola spring scale). The air temperature at ground level was 19.8° C and the surface water temperature near shore was 21.8° C.

I counted 74 (57%) living *Rana utricularia* metamorphs and 55 (43%) dead. Emigration of metamorphs did not begin until sunset; therefore emigrants were exposed to an undetermined number of passing vehicles for approximately one hour. The number of frogs killed by vehicular traffic seems high considering that the road is a dead-end and only twelve families live beyond the pond. However, since *R. utricularia* migrate principally after dark (Pechmann and Semlitsch, *op. cit.*), a migration pulse is likely immediately after sunset, resulting in a relatively high emigration rate.

The percentage of emigrating frogs killed is probably inflated because some frogs may have successfully crossed the road prior to my arrival. Some dead frogs also may have been undetected because they were generally flattened to the level of the road surface and did not attract attention by movement. Still, frog mortality can be high during migration periods on a lightly traveled secondary road when the road is adjacent to a breeding pond.

The published rates at which frogs are killed on roads as determined by diurnal road cruising can be misleading. For example, *Rana pipiens* was killed at the rate of 0.002 frogs/km (Scott, *op. cit.*); McClure (*op. cit.*) found 0.0008 frogs/km; and Christoffer (*op. cit.*) found one *Bufo* killed (.0002 frogs/km). Diurnal estimates imply that vehicular traffic is not a threat to frog populations. Surveys of anuran habitat under meteorological conditions conducive to frog movement reveal a much different picture. Immediately following a storm, Scott (*op. cit.*) observed 10 dead frogs/m^2 along 0.8 km of highway adjacent to a marsh. Gelder (1973. Oecologia 13:93–95) recorded the death of 122 *Bufo bufo* along 1.5 km of road near breeding ponds in 84 nights of observation. My observations document the death of 55 *Rana utricularia* metamorphs along 0.3 km of road adjacent to a pond. These results underscore the need to assess the mortality of amphibians on roads nocturnally under proper meteorological conditions. Although quantitative data regarding the impact of vehicular traffic on amphibians is available for some European species (Langton 1989. Amphibians and Roads. ACO Polymer Products Ltd., Bedfordshire, England), few data are available for North American amphibians. Better understanding of the effect of vehicular traffic on amphibian populations will require nocturnal surveys, particularly during, or immediately following, precipitation, and surveying on foot.

I thank C. Kenneth Dodd, Jr. for providing references and reviewing the manuscript.

CROCODYLIA

ALLIGATOR MISSISSIPPIENSIS (American Alligator). **NESTS**. We discovered two unusually constructed alligator nests at Brazos Bend State Park, Fort Bend Co., Texas during 1992. Alligators typically build terrestrial mound nests composed of plant material and soil. One nest found on 29 July possessed an egg cavity completely below ground level. The nest measured 31.8 cm at its highest point, and the uppermost egg was 7.6 cm below ground level. It was composed primarily of soil mixed with some sticks and finer plant material. Although we documented four nests that were lower in height, none had eggs in a subterranean cavity. A nest discovered on 30 June was unusual in that it was built on a pile of logs surrounded by water. A previous study of nesting at the park showed that islands were preferred nesting sites over banks (Hayes-Odum et al. 1993. Texas J. Sci. 45:51–61). However, islands used for nesting were well defined areas of land many times larger than the nests. This pile of logs extended >l m out of the water, and thus afforded substantial protection from flooding. Nest material consisted of grass, leaves, and soil.

This research was supported under NSF grant TPE89-55157. We are grateful for the assistance of Frank Hoot who provided access to remote nests via airboat.

TESTUDINES

CARETTA CARETTA (Loggerhead Sea Turtle). **DIURNAL NESTING**. Among the sea turtles, diurnal nesting is well known in only the Kemp's Ridley, *Lepidochelys kempi*, and occasionally in the Olive Ridley, *Lepidochelys olivacea*, especially during peak arribadas (Pritchard et al. 1983. Manual of Sea Turtle Research and Conservation Techniques. Center For Environmental Education, Washington, D.C. 126 pp.). During the 1992 and 1993 nesting seasons, researchers on Wassaw National Wildlife Refuge, Chatham County, Georgia were fortunate to view two loggerhead sea turtles (*Caretta caretta*) which nested during daylight hours.

On 23 June 1992, an untagged loggerhead possessing no previous signs of tagging (CCL=101.0; tags: QQP768, QQP784, 0000158E46) was found as it emerged from the surf at 1300 h on Wassaw Island. The turtle emerged just prior to high tide, crawled above the high water mark, and nested. The day was sunny and notably hot (ca. 35°C). The turtle was seen again during two additional nesting visits in the 1992 season, both of which occurred at night.

On 1 July 1993, a loggerhead tagged during a previous season (CCL=102.0 cm; tags: QQB144, QQZ077, 00001582BA) emerged from the water at 1645 hours. As in the previous case, this turtle also emerged just prior to high tide, crawled up the beach, and nested on this sunny, hot day. This turtle had been observed on two other nesting crawls during the 1993 season, both of which were at night.

TABLE 1. Observations of diurnal nesting of *Caretta caretta*.

Source	Number	Time	Location
Caldwell et al. 1959. Bull. Florida State Mus. 4:295–308.	3	dawn–0905 h	South Carolina Georgia, Florida
Fritts and Hoffman. 1982. J. Herpetol. 16:84–86.	7*	0540–1930 h	Florida
Bustard, R. 1973. Sea Turtles, Their Natural History and Conservation. Taplinger Publ. Co. 220 pp.	Several	1630–1725 h	Australia
LeBuff, C. H., Jr. 1990. The Loggerhead Turtle in the Eastern Gulf of Mexico. Caretta Research Inc. 216 pp.	2	1130 h, 1140 h	Florida

*One *Chelonia mydas* was also observed nesting in daytime during this study.

Some authors (Bustard 1973. Sea Turtles, Their Natural History and Conservation. Taplinger Publ. Co.; Fritts and Hoffman 1982. J. Herpetol. 16:84–86) suggested daytime emergences are timed with high tides. In the two examples of diurnal nesting on Wassaw Island reported here, the turtles emerged approximately 45 min prior to high tide. However, other turtles have been observed through the years on Wassaw during twilight hours of the day or night, either beginning or ending their land activities in full daylight. One such example was an untagged loggerhead found on 22 June 1985 at 0547 h as she emerged from the water, one hour after the tide had begun to flood. After crawling about 85 m, the turtle (SCL = 91.0 cm; tags: GA6791; GA6815) began digging a nest at 0602 h and did not return to the water until well after daylight.

On Wassaw Island, one out of 139 (0.72%) crawls in 1992 and one out of 57 (1.75%) crawls in 1993 were confirmed as diurnal. Observations by other researchers (Table 1) confirm that diurnal nesting behavior in loggerheads is extremely rare.I thank the U.S. Fish and Wildlife Service, the Wassaw Island Trust, and the Skidaway Island Boat Club for their continued help and support of the Caretta Research Project. Special thanks is extended to all the volunteers who participated in this program since its inception in 1973.

CARETTA CARETTA (Loggerhead Sea Turtle). **PREDATION**. Marine turtles are threatened throughout the world by various biotic and abiotic factors, either natural or man-induced, including incidental catch, pollution, disappearance of suitable nesting sites, and predation. At nesting beaches predation is generally limited to eggs and hatchlings (Frazer 1992. Cons. Biol. 6:179–184; Pritchard 1980. Amer. Zool. 20:609–617). Mortality of nesting females by large terrestrial predators has been documented rarely. This note reports predation of nesting female loggerhead turtles, *Caretta caretta* by golden jackals.

During June–August 1991 and June–September 1992 we studied the loggerhead population breeding on the beaches of the Göksu Delta, on the Turkish Mediterranean coast, 80 km west of Mersin. Based on the numbers of nests observed during daily beach patrols and assuming an average clutch frequency of 3 nests per female per season (Frazer and Richardson 1985. Herpetologica 41(3):246–251; Talbert et al. 1980. Copeia 1980(4):709–718), we concluded that in the Delta 45 (1991) and 35 (1992) *C. caretta* had nested. In both years several nesting females were killed by large canid predators. These females, 4 in 1991 and 3 in 1992, represented approximately 10% of the nesting females in each year.

All evidence clearly indicated that the predator involved was the golden jackal, *Canis aureus*. Although predation was never observed by us, numerous canid footprints, all of jackal shape and size, were found around dead females. The delta supports a population of golden jackal (D.H.K.D. 1992. Towards Integrated Management in Göksu Delta, a Protected Special Area in Turkey, Feasibility Report. Istanbul. 272 pp.), and additionally, local fishermen claimed to have observed jackals attacking sea turtles on the beach.

The female turtles were usually killed soon after emerging from the sea, even before the start of nest excavation. Tracks and prints at the sites indicated that the jackals operated either alone or in groups of a few individuals, and that turtles were often killed after a short struggle. They were attacked at the neck and opened via the shoulder, through which some of the viscera were removed. Several carcasses were thoroughly cleaned out, others only partly devoured and one individual was left almost intact.

Predation of adult sea turtles by terrestrial predators has never been reported before in the Mediterranean. Worldwide, only few anecdotal or speculative data are available and the impact on turtle populations is thought to be minimal (Márquez 1990. FAO Fisheries Synopsis. No. 125, Vol. 11. Rome. 81 pp.; Stancyk 1982. *In* K. A. Bjorndal (ed.), Biology and Conservation of Sea Turtles, Washington D.C., pp. 139–152). However, withdrawal of reproductive females has a relatively large impact on a population and the effect of jackal predation on this vulnerable *C. caretta* population could be profound if it continues on this scale tor several years.

We are grateful to Nafiz Güder, Vincent van den Berk, and Alice Carswell of D.H.K.D. We would especially like to thank Lorna Brown. This study was supported by D.H.K.D., Turkey, Van Tienhoven Stichting and Stichting Nijmeegs Universiteitsfonds, The Netherlands.

CHELONIA MYDAS (Green Turtle). **PREDATION**. During a three month sea turtle tagging and monitoring program in 1991 on Gielop Island (9°56'N, 139°54'E), Yap State, Federated States of Micronesia, coconut crabs (*Birgus latro*) were observed feeding on naturally emerged hatchling green turtles. In addition, coconut crabs were found preying on green turtle hatchlings which had surfaced into open-top nest enclosures. One could periodically observe one or two coconut crabs a night, sometimes for several nights in a row, eating hatchling green turtles.

Coconut crabs were not observed to burrow down to nest eggs, as has been noted in the Seychelles Islands by Honegger (1967. British J. Herpetol. 4:8–11). However, coconut crabs were frequently sighted scavenging sea turtle eggs which were strewn from previously laid nests by nesting green turtles.

Other observed land predators of hatchling green turtles at Gielop Island include ghost crabs (*Ocypodes* sp.) and hermit crabs (Paguridae).

GRAPTEMYS GEOGRAPHICA (Common Map Turtle). **PARASITES**. On 28 June 1993, an adult female *Graptemys geographica* was captured by hand as it foraged in 250 mm of water. The capture site was on the northern edge of Sand Point, Bellows Bay, Ottawa River, Westmeath Tp., Renfrew Co., Ontario, Canada. The turtle was host to six leeches. Three of the leeches were the commonly encountered turtle leech *Placobdella parasitica* (ROMIZ I2188). The remaining three leeches were *Placobdella ornata* (ROMIZ I2187). This is the first observation of parasitism by *P. ornata* on *G. geographica*. One of the *P. ornata* was attached to the ventral surface of the marginal scute located immediately posterior to the left plastral bridge. The second *P. ornata* was affixed to the bottom of the turtle's left posterior foot. The last *P. ornata* was similarly placed, but on the right posterior foot. All three *P. parasitica* were found in the posterior axial area, on the integument anterior to the limbs.

On 25 August 1993, a juvenile *G. geographica* (CL=91.55 mm; CW=78.35 mm; Pl=79.5 mm; PW=40.25 mm) was captured in a hoop trap at the Big Creek National Wildlife Area, Long Point, Haldimand-Norfolk Co., Ontario, Canada. Only one *P. ornata* (ROMIZ I2186) was found attached to this specimen. The leech was affixed to the right femoral scute of the turtle.

On 26 May 1993, five adult female, two male, and three other small *G. geographica* were observed basking on a single large boulder in 450 mm of water on the north shore of the Ottawa River, 1.5 km S. and 2.0 km E. of the eastern most tip of Cranson Lake, L'Ile-aux-Allumettes Tp., Pontiac Co., Québec, Canada. All turtles dove off the rock upon being approached. A *P. ornata* (ROMIZ I2185) was found on the boulder moving at a rate of 2.2 mm/s to the water's edge in bright sunlight, on a dry substrate. This is the second report of a leech becoming separated from its host during thermoregulation (Vogt 1979. Auk 96:608–609).

The following individuals and organizations contributed generously through grants and equipment for research on turtles: World Wildlife Fund; Ontario Ministry of Natural Resources; Québec Ministère Loisir, Chasse, et Pêche; Jeff Robinson, Canadian Wildlife Service; Dr. Francis Cook and Mike Rankin, Canadian Museum of Nature; Maureen Zubowski and Ross MacCulloch, Royal Ontario Museum; Stuart Niven, Vanier College Research Station; Dr. Roger Bider, St. Lawrence Valley Natural History Society.

SAURIA

CRYPTOBLEPHARUS POECILOPLEURUS (Snake-eyed Skink). **ACTIVITY**. Crombie and Steadman (1986. Pac. Sci. 40:44–57) characterized the species, in the Cook Islands, as preferring sunny habitats, being strictly diurnal and active between 0800 and 1700 h. McCoid and Hensley (1993. Herpetol. Rev. 24:87–88) reported nocturnal behavior under special conditions. Herein, we report on emergence times and activity periods for a population of *C. poecilopleurus* from Cocos Island, a small atoll (37 ha) 2 km south of Guam, Mariana Islands. The population on Cocos Island is entirely arboreal and primarily found in *Casuarina equisetifolia* (Australian Pine) groves. Activity surveys (N = 6, 1989–1990) were begun before dawn and generally continued until approximately 1000 h, with occasional surveys (N = 4) made at sunset. Temperatures ranged daily between 22° and 33°C. On clear to partly cloudy days, emergence of the skinks occurred at dawn (0630 h) and they were found < 1 m from the ground in sunlit areas on bases of trees. By 0900 h, lizards could be observed on bases of trees, up to 2 m from the ground, and by 1100 h, they could be observed foraging over the entire tree, as high as 10 m. Approaching sunset (>1600 h), the *C. poecilopleurus* returned to the ground and basked in sunlit areas near the base of the trees. These observations suggest that nocturnal refugia were at bases of occupied trees, probably beneath loose bark or in root masses. On cloudy days, emergence might be delayed for one to two hours, or until air temperatures reached 26–28°C. On windy days (estimated 32–50 kph), emergence might also be delayed about an hour. Tropical Storm conditions (>72 kph wind) suppressed emergence. Rain suppressed emergence, or forced early retreat to refugia. Occasional light showers did not appear to affect activity. *Cryptoblepharus poecilopleurus* was also observed to be consistently spaced on occupied trees. Usually one, and never more than three *C. poecilopleurus*, were observed on a single tree; trees with trunk diameter >2.5 cm usually were occupied. Placement of several individuals into a single bag always resulted in the loss of tails of all the individuals. They would continuously fight unless sufficient detritus for refugia was also placed in the bag. Interaction with other species of scincids in the same bag was not noted, however. This intraspecific aggression may account for the observed spacing of free-living *C. poecilopleurus*.

Portions of this research were supported by the Endangered Species Conservation Program, Project E4 (to Guam).

ELGARIA KINGI (Arizona Alligator Lizard). **SIZE**. On 30 July 1992 at 1936 h, I captured a large male Arizona alligator lizard (*Elgaria kingi*) in the Camp Geronimo Boy Scout Preserve, Gila County, 6 km east of Pine, Arizona. This specimen (Arizona State University Herpetology Collection #29011) measured 133 mm SVL, 114 mm tail length, and weighed 37.5 g. In my measurements of >400 alligator lizards throughout Arizona, this was the largest specimen ever encountered. Both Stebbins (1985. A Field Guide to Western Reptiles and Amphibians, 2nd Ed, Houghton Mifflin Co, Boston, Massachusetts, 336 pp.) and Smith and Brodie (1982. A Guide to Field Identification Reptiles of North America, Golden Press, New York, 240 pp.) list the maximum SVL of *E. kingi* as 125 mm and 127 mm, respectively. Both listings are substantially less than the 133 mm SVL of this specimen from Camp Geronimo.

Submitted by **ROBERT W. BOWKER**, 2030 E. Colgate Dr., Tempe, Arizona 85283, USA.

SCELOPORUS MAGISTER (Desert Spiny Lizard). **CANNIBALISM**. Although *S. magister* is commonly reported to include other lizards in its diet (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Company, Boston, Massachusetts. 336 pp.), the literature contains few specific references. Vitt and Ohmart (1974. Herpetologica 30(4):410–417) reported one juvenile *Cnemidophorus tigris* among 1897 prey animals found in the stomachs of 66 *S. magister*. Parker and Pianka (1973. Herpetologica 29(2):143–152) reported one vertebrate out of 7928 prey items removed from 123 specimens of *S. magister*. Knowlton and Thomas (1934. Utah Acad. Sci., Arts, and Let. 11:257–259) reported a small *Cnemidophorus tessellatus* consumed by *S. magister*. The only previously documented case of conspecific cannibalism occurred at the Nevada nuclear test site where a hatchling *S. magister* was discovered in the stomach of one of 21 adults examined (Tanner and Krogh 1973. Great Basin Nat. 33(3):133–146).

This report provides the third account of lizard predation by *S. magister* and the second account of conspecific cannibalism.

On 8 August 1993, I collected a female *S. magister* (SVL = 69 mm) at 0740 h PST among granite boulders on a sunny south facing desert hillside at 955 m elevation in the town of Apple Valley, San Bernardino County, California (T5N, R4W, Sec 2, NW 1/4). Seconds after capture, the animal spontaneously regurgitated a conspecific neonate (SVL = 36 mm; tail = 73 mm, tip missing; mass = 1.4 g). A dark umbilical wound was visible. Mass of the larger animal was 13.3 g after regurgitation. Photographs of dorsal and ventral views of the regurgitated animal are deposited at the University of Texas at Arlington, UTA slide nos. 17023 and 17024.

I thank William W. Lamar for valuable suggestions about literature for this paper.

Submitted by **MICHAEL CARDWELL**, P.O. Box 492, Victorville, California 92393-0492, USA.

SCELOPORUS OCCIDENTALIS. (Western Fence Lizard). **ASSOCIATION.** On 18 March 1993, while hiking in the Los Padres National Forest, Santa Barbara County, California, USA, I noosed an adult male *Sceloporus occidentalis*. This lizard had a thin layer of bright golden/yellow pollen over its entire dorsal surface, from the snout to the tip of the tail, including the appendages and digits. The lizard was found in a Coast Live Oak Woodland (119°56'15"E and 34°45'09"N) that included *Quercus agrifolia, Pinus sabiniana, Ceanothus megacarpus, Ribes speciosum, Juglans californica,* and *Eriogonum* sp. Other *S. occidentalis* (N = 4) in the immediate vicinity possessed no obvious pollen encrustations.

Visual inspection of the lizard with a dissecting scope indicated a coarse, granular film of pollen over the entire dorsum. No pollen was observed on the ventral surface. The film of pollen was attached to the lizard in such a way that removing it was difficult without the aid of a scraping tool. The pollen could not be identified to species, but was of a grass (family Poaceae) (Henrickson, pers. comm.). It is unlikely that the *S. occidentalis* is involved with plant reproductive strategies since it is predominantly an insectivore; it may, however, become incidentally involved with pollination.

The pollen coating poses several problems to the lizard, such as: l) thermoregulation; 2) social behavior; and 3) pineal organ function (as the parietal eye was also covered by the pollen). Some of the thermoregulatory functions would appear to be influenced by the light coloration and the coating of the pollen, such as heat absorption and heat dissipation. Intraspecific behavioral interaction may be affected because of the yellow pollen-coated dorsal coloration. This individual would seem conspicuous to predators because of its bright golden/yellow coloration as this was how the lizard was noticed by the author, a potential predator! The pineal organ and ultimately circadian rhythm and thermoregulation might be impaired in this individual as a result of the pollen coating.

I thank B. H. Brattstrom for intellectual input and reviewing this manuscript, J. Burk and C. E. Jones for their assistance in the SEM laboratory, S. Karl for preparing the SEM specimen, and J. Henrickson for assistance with pollen identiflcation.

UROSAURUS ORNATUS (Tree Lizard). **SPERM STORAGE.** Females of many lizard species are capable of storing sperm in the oviducts during the reproductive season (Cuellar 1966. J. Morph. 119:7–20). While sperm may remain viable in the lizard oviduct for as long as 7 months (Porter 1972. Herpetology. W. B. Saunders Co., Philadelphia, pp. 388–390), duration of viable sperm storage is unknown for most phrynosomatid lizards. To ascertain whether over-winter sperm storage occurs in *U. ornatus*, we looked for sperm in females that had definitely produced offspring or mated in the previous season, and subsequently over-wintered with no access to males.

Twenty female *U. ornatus* were captured at Aguirre Spring Recreation Area at 1700 m elevation in the Organ Mountains (32°22'N, 106°33'W, Doña Ana County, New Mexico) 6–8 April 1992. Lizards were maintained at New Mexico State University, Las Cruces, New Mexico, USA. Thirteen females were housed individually with a mature male in semi-natural outdoor pens measuring 2 X 2 m. The remaining seven females were housed together in a similar pen with a single male. Ten of the 13 singly-housed females laid from one to three clutches of eggs that hatched in the pens. At least three of the grouped females laid viable clutches, but we could not determine which females produced these clutches. At the end of the activity season (October 1992) the females from both groups were placed together, in the absence of any males, in one pen to overwinter. In late April 1993, the females, all of which survived hibernation, were preserved in 10% neutral buffered formalin and deposited in the Natural History Museum of Los Angeles County (LACM 140868–140887).

Histological examination of the oviducts did not reveal the presence of sperm in any of the females, even though there were vaginal folds similar to those shown to store sperm in *Sceloporus jarrovii* (Goldberg 1970. Ovarian Cycle of the Mountain Spiny Lizard *Sceloporus jarrovi* Cope. Ph.D. Thesis, The University of Arizona, Tucson, 115 pp.). This raises the possibility that *U. ornatus* females may store sperm during the breeding season. However, our observations indicate that no over-winter sperm storage occurred. Thus, for *U. ornatus*, it appears that production of offspring in a given year is dependent on inseminations during that particular year.

SERPENTES

CLONOPHIS KIRTLANDII (Kirtland's Snake). **SUBTERRANEAN PREY CAPTURE.** *Clonophis kirtlandii* is a secretive snake, known to feed on earthworms, slugs, leeches, crayfish, and fishes (Conant 1938. Am. Midl. Nat. 20:1–200; Minton 1972. Indiana Acad. Sci. Monogr. 3:v + 1–346; Tucker 1977. Bull. Maryland Herp. Soc. 13:193–195; Bavetz, pers. comm.). No observations have been published concerning how this species captures its prey.

A simulation of the normal environment of free ranging *C. kirtlandii* was made using an aquarium (92 cm x 31 cm x 43 cm) modified by placing a partition 19 cm from the top of the tank. This partition was 23.5 cm long and joined to a vertical partition extending from the bottom of the tank. The vertical partition was set 7.5 cm from the front of the tank. These two partitions formed a chamber that was filled to a depth of 82 cm with soil obtained from the site where the snakes were caught. The portion of the tank not filled with soil was filled with water to a depth of 6 cm to keep the soil moist.

Observations were conducted intermittently between 1900 and 2400 h each night during a two week period. During observations the tank was lit by ambient light from the fixtures in the room.

A total of 60 earthworms (*Lumbricus* sp.) were allowed to adjust to the tank for one week, during which time they formed a series of burrows within the observation chamber which allowed their behavior to be observed.

Four specimens of *C. kirtlandii*, two males (TL = 430 and 425 mm) and two females (TL = 210 and 461 mm), from Effingham, Illinois (Brown et al. 1975. Herpetol. Rev. 6:78–79) were placed in the aquarium. These snakes had been maintained on a diet of earthworms and were feeding well. No period of starvation was used to stimulate feeding.

The snakes were observed feeding on 12 occasions. In three instances, snakes were observed to emerge from hiding places and assume a Z-shaped alert posture, with the head up. When an earthworm was exposed in the vicinity of the snake, tongue flicking increased, and the snake searched for and attacked the earthworm. On five other occasions, snakes that were initially seen in the Z-shaped alert posture were later observed swallowing earthworms. On many occasions, snakes seen in the Z-shaped alert posture retreated to their refugia without attacking or feeding.

On two occasions, *Clonophis* seen within earthworm burrows attacked and swallowed the earthworm occupying the burrow. On two other occasions, snakes were found swallowing earthworms inside burrows. Snakes were not seen pursuing an earthworm into a burrow. In no instance, did the earthworms react to the presence of the snake until bitten.

This is the first report of feeding within earthworm burrows for *C. kirtlandii*. However, that the snakes enter earthworm burrows in search of prey should be expected considering the adaptations for fossorial existence present in the species (Conant 1943. Am. Midl. Nat. 29:313–341).

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **RECORD RATTLE-STRING**. In August, 1985, the first author (DC) captured a male *Crotalus v. viridis* (Rafinesque) in the vicinity of Pawnee Buttes, Weld Co., Colorado. The snake was maintained in his laboratory at the University of Colorado in Boulder, until its death 2 August 1993. It is now preserved as no. 56799 in the University of Colorado Museum herpetological collection.

At the time of death the snake measured 879 mm SVL, tail 58 mm. Its only obvious unusual feature is its record rattle-string of 38 segments. All segments have approximately the same maximum dimension of 12 mm, and the string is of uniform diameter throughout its 135 mm length. Hence it is incomplete by at least ten or twelve segments by Klauber's (1956. Rattlesnakes: Their Habits, Life Histories and Influence on Mankind. Univ. California Press, Berkeley and Los Angeles. p. 252) generalization—the point at which little or no further change in lobe size occurs. The terminal dozen or so segments bear small, irregular indentations, progressively more apparent toward the distal end of the string.

This rattle-string is much longer than any previously reported (of authentic integrity; Klauber, *op. cit.*: 250–260 discussed many longer ones of unacceptable authenticity) for either captive or freshly captured specimens, of any species of rattlesnake. Klauber (*op. cit.*: 260) cited records of 17 for a complete string (in *C. adamanteus* Beauvois) and 23 for an incomplete string (in *C. atrox* Baird and Girard) in freshly caught specimens, and 18 for a complete string (in *C. tortugensis* Van Denburgh and Slevin) and 29 for an incomplete string (in *C. horridus* Linnaeus) in captive specimens. The present string is therefore nine segments longer than any previously recorded in its category (incomplete string in a captive specimen), and the longest for any category.

The exceptional length of the string of 38 segments was probably attained as a result of several factors, including the unusually mild temper of the snake, the simplicity of its quarters (minimizing the chance of catching the rattle string on an obstacle, or of wearing it against abrasive surfaces), the infrequency of assuming a protective or resting coil together with the relatively light weight of the snake (minimizing the chance of catching the string under the snake's body), the damping effect through inertia of distal segments when the string was shaken, and the regular offering of dead food. Under such conditions a potential exists for growth of even longer strings in this and other species.

DIADOPHIS PUNCTATUS PUNCTATUS (Southern Ringneck Snake). **ANTI-OPHIOPHAGOUS BEHAVIOR**. Small snakes may be especially susceptible to predation by ophiophagous snakes. Here, we report one observation of a captive longnose snake (*Rhinocheilus lecontei lecontei*) attempting to feed upon a *Diadophis p. punctatus* which suggests a possible defense against ophiophagy by *D. p. punctatus*.

We placed a 275 mm TL *D. p. punctatus* collected in Hillsborough County, Florida, in a glass aquarium measuring 61 x 30 x 25 cm which housed a 640 mm TL *R. l. lecontei* collected in Pima County, Arizona. The *Rhinocheilus* immediately approached and seized the *Diadophis* by the tail. Instead of struggling the *Diadophis* remained motionless and was swallowed almost entirely (tail first) before moving. When the head of the *Diadophis* entered the mouth of the *Rhinocheilus*, it turned its head 90°, and bit the floor of the larger snake's mouth. After 6 h in this position the *Diadophis* was regurgitated but not released, and the *Rhinocheilus* positioned for a mid-body approach. Once again, when the smaller snake's head entered the mouth of the larger, the biting response was repeated, which again resulted in an apparent deadlock lasting roughly 6 h. The whole cycle was repeated for a third time.

The *Rhinocheilus* remained motionless after 16 h from the beginning of these observations, and was presumed to have died shortly thereafter. Seventeen hours after the initial attack, the *Diadophis* slowly worked its jaws free and crawled out of the now dead *Rhinocheilus*.

This behavior and its fatal consequences raises several questions. Was the *Rhinocheilus* envenomated by the ringneck? *Diadophis punctatus* has enlarged saber-like teeth at the posterior end of the maxillary bones and there are several anecdotes of bites from this species causing a burning sensation (Myers 1965. Bull. Florida St. Mus. Biol. Sci. 10:43–90.). Myers (*op. cit.*) also reported that other forms of *Diadophis* salivate copiously when handled excessively.

The authors thank Joseph A. Butler and Lee A. Fitzgerald for their helpful comments.

Submitted by **JOHN V. ROSSI**. Division of Science and Mathematics, Jacksonville University, Jacksonville, Florida 32211, USA, and **ROXANNE ROSSI**, North American Snake Institute, 7451-13 103rd St. Suite 68, Jacksonville, Florida 32210, USA.

DRYMARCHON CORAIS COUPERI (Eastern Indigo Snake). **PREY**. The diet of the eastern indigo snake includes a variety of mammals, birds, reptiles (and their eggs), amphibians, and fish (Ernst and Barbour 1989. Snakes of Eastern North America. George Mason Univ. Press. Fairfax, Virginia, 282 pp.). Few invertebrates have been reported.

On 17 May 1993, a juvenile eastern indigo snake measuring 61 cm TL was captured in Baker County, Florida. Within several minutes of capture, the snake regurgitated a large slug, *Philomycus* sp. The slug was approximately 7.5 cm in length.

Philomycus slugs are numerous in some areas of Florida and may be an important food source for the secretive hatchling and juvenile indigo snakes in certain microhabitats.

The authors thank Kurt Auffenberg for his assistance in identifying the slug and Lee A. Fitzgerald for his helpful comments.

ELAPHE OBSOLETA (Rat Snake) **REPRODUCTION**. According to Plummer (1990. Herpetologica 46(2):190–195), "nesting in hollow trees is unknown for snakes other than *Opheodrys aestivus*...." However, W. M. Palmer, of the North Carolina Museum of Natural History (1993, pers. comm.), is aware of an incident of *Elaphe obsoleta* nesting in a tree cavity in North Carolina and another in Virginia. This note documents an occurrence of *E. obsoleta* nesting in a tree cavity.

On 12 June 1992, fourteen snake eggshells were discovered in a cavity of a beech tree (*Fagus grandifola*) 2.5 miles N of Elizabeth City, Pasquotank County, North Carolina. The tree was in a wooded area with the upper portion removed and cut into sections which exposed the nest cavity. The cavity opening was located 6.0 m above the ground.

The cavity opening appeared to be a rot hole from a broken limb and measured 20.8 x 11.7 cm. The cavity was approximately 0.07 m^3 (39 x 33 x 93 cm). It was about half full of decomposed wood and contained what appeared to be a squirrel (*Sciurus* sp.) nest.

Most of the eggshells exhibited typical longitudinal slits like those made during hatching. Two contained irregular holes which suggest they did not hatch. The two eggs that apparently did not hatch retained their near-natural shape. The more perfect of the two measured 41 x 23 mm which is consistent with egg size for *E. obsoleta* (Ernst and Barbour 1989. Snakes of Eastern North America. George Mason University Press. Fairfax, Virginia. 282 pp.). The size and surface texture of the eggshells are consistent with other *E. obsoleta* eggs found previously in the Elizabeth City area by the author (Brothers 1965. J. Elisha Mitchell Sci. Soc. 81(2):119–124). The eggs of *Coluber constrictor* have a coarse texture, and *Elaphe guttata* is not known from the area despite many years of observations (Brothers, *op. cit.*, pers. obs.). The North Carolina Museum of Natural History considers the eggshells as those of *E. obsoleta* (NCSM 32025).

I thank Leroy Seier for making me aware of the find and allowing me to visit the site and W. M. Palmer for comments on the manuscript.

EUNECTES MURINUS GIGAS (Northern Green Anaconda). **CANNIBALISM**. There are very few reported instances of true intraspecific cannibalism amongst the boids (Mitchell 1986. Cannibalism in Reptiles: A Worldwide Review. SSAR Herpetol. Circ. No. 15:1–37) .

We removed a live female *Eunectes murinus gigas*, 1940 mm SVL (2320 mm TTL), from a nylon monofilament fisherman's gill net set above rapids, along the Guyanese bank of the Ireng River on the Guyana/Brazil border at Orinduik, western Guyana on 6 September 1993.

Shortly after capture the anaconda disgorged the recognizable remains of a smaller conspecific. Due to the advanced state of decomposition it was impossible to determine the exact length (ca. 1.5 m TTL), sex, or cause of death of the cannibalized specimen. The live individual was released. *Eunectes murinus* is a known predator of mammals, waterbirds, and caiman, but I have been unable to locate any reports of ophiophagy or cannibalism for this species in the wild. However, Holmstrom and Behler (1981. Zool. Garten NF, Jena 51 (5/6):353–356) and Neill and Allen (1962. Quart. J. Florida Acad. Sci. 25:73–75) reported ingestion of extraembryonic membranes and an undeveloped egg, and aborted embryos by adults in captivity. Live neonates were not eaten.

I thank Col. John Blashford-Snell and Julian Matthews for inviting me to participate in the "Land of El Dorado Expedition" and all the members of the expedition and the Guyanan Defense Force who assisted with the herpetological/ichthyological surveys. Particular thanks go to Darren Finch of London and Mr. Chung of Orinduik. This fieldwork was funded by Discovery Expeditions of Motcombe, near Shaftesbury, Dorset, England.

LAMPROPELTIS PYROMELANA (Sonoran Mountain Kingsnake). **TEMPERATURE, ACTIVITY**, and **SIZE**. During the past 11 yrs (1983 to 1993), I documented activity temperatures, times when observed, and body size on a population of the little known Sonoran mountain kingsnake (*Lampropeltis pyromelana*) at Camp Geronimo Boy Scout Preserve, 6 km E Pine, Arizona at the base of the Mongollon Rim. I gathered data on 11 snakes that were active (none was found by log or rock turning). An additional 69 snakes, brought in by campers and staff, were measured to assess population size structure.

Average body temperature of the 11 active snakes was 26.8°C ± 0.60 SE (range 23.0–29.2) and was significantly correlated with air (26.7°C ± 0.79 SE; range 20.0–29.8; $r = 0.615$, $P < 0.05$, $df = 10$) and substrate (25.2°C ± 0.91 SE; $r = 0.75$, $P < 0.01$, $df = 10$) temperatures. Brattstrom (1965. Am. Midl. Nat. 73:376–422) gave the mean body temperature for *L. zonata*, a kingsnake with a similar habitat to *L. pyromelana*, at 27.5°C. *Lampropeltis pyromelana*, like many squamate species in shaded habitats (Huey and Slatkin 1976. Quart. Rev. Biol. 51:363–384), appears to be a thermoconformer to air and substrate temperatures.

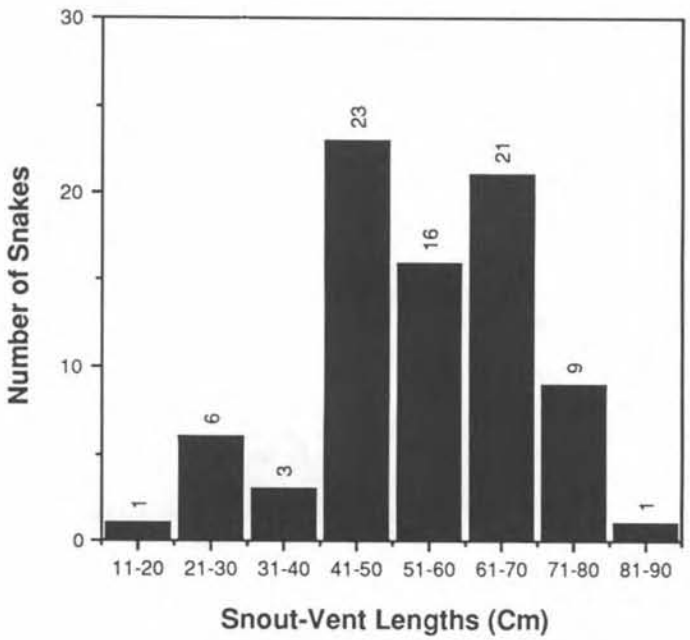

FIG. 1. Age distribution of *Lampropeltis pyromelana* in the Theodore Roosevelt Preserve of Camp Geronimo.

Over 470 h (from April to October) were spent searching for kingsnakes and only 11 activity records were recorded, a rate of 1 snake every 42.8 h of search time! Despite the small sample, a diurnal activity pattern is evident. All snakes were captured between 1140 and 1810 h. Peak activity (3 captures) was between 1500 and 1600 h, a rate of 1 snake every 12.7 field h. A yearly activity cycle is also evident in this small sample; 8 of the 11 snakes were found in July and August, a rate of 1 snake every 22.6 h of field time. All 8 snakes from July and August were above 41 mm SVL; therefore, hatchlings have not inflated this figure.

Size range for individuals in this population was between 19.5 and 88 cm SVL, with most (75%) snakes measured between 41 and 70 cm SVL (Fig. 1). Hatchlings were brought in during July and August and were between 19.5 and 27 cm SVL. Sex of the snakes could not be accurately determined.

Absence of recapture data from 40 marked and released snakes suggests a large population. However, the low probability of encountering an active snake and the rarity that campers and staff encountered this species suggests that density may be low and also may indicate that this species is wide-ranging or very secretive.

I am grateful to the staff of the Camp Geronimo Boy Scout Camp for making their property available to me and providing me with snakes to measure. Additionally, I am grateful to the hundreds of boy scouts that directly or indirectly contributed snakes for this study.

PITUOPHIS MELANOLEUCUS DESERTICOLA (Great Basin Gopher Snake). **BEHAVIOR**. We report here on an unusual encounter in the wild between a *Pituophis melanoleucus deserticola* and a golden-mantled ground squirrel (*Spermophilus lateralis*).

On 28 May 1993, in a small limestone canyon near the Colorado-Utah border in Dinosaur National Monument, Uintah Co., Utah we found a ground squirrel challenging a *P. m. deserticola* of approximately 165 cm TL. The ground squirrel was making no attempt to flee its potential predator, which was loosely coiled in low vegetation and obviously had eaten recently. If the snake moved, the ground squirrel would feign a charge or actually dart in to attack the snake, usually about the head, and then quickly retreat to a log 40 cm from the snake. The ground squirrel appeared to be defending the area around the log. Despite the attacks, the snake, which had been bloodied below its left eye, also was not making an attempt to depart.

We observed this encounter from a stream bank at a distance of 2 m for 10 min. The temperature was 22–25°C under sunny skies. The encounter ended when the ground squirrel was frightened away by a flash from our camera. At that time, we captured the snake, and it was easily observed that it had recently eaten two prey items.

We know of no other observation in the wild where a *P. melanoleucus* was held at bay by a ground squirrel or other potential prey. We believe the ground squirrel was defending a nest in the vicinity of the log, because 15 min after we released the snake, the ground squirrel returned to the log and appeared to search for the snake in the area of the confrontation.

Submitted by **RICHARD M. ENGEMAN**, Denver Wildlife Research Center, USDA/APHIS/ADC, P.O. Box 25266, Bldg 16, Denver Federal Center, Denver, Colorado 80225-0266, USA, and **JAMES J. DELUTES III**, P.O.Box 1623, Boulder, Colorado 80306, USA.

PYTHON SEBAE (African Rock Python). **REPRODUCTION**. The reproductive biology and breeding behavior of the African pythons are poorly known, even for the large *Python sebae* (Branch 1988. Field Guide to the Snakes and other Reptiles of Southern Africa. New Holland, Ltd. Cape Town, South Africa. 328 pp; Pitman 1974. A Guide to the Snakes of Uganda. Wheldon and Wesley, Ltd. Codicote, England. 290 pp.; Starin and Burghardt 1992. The Snake 24:50–62). There appear to be no published accounts of the behavior of neonates of any of the large pythons at the nest site; therefore observations of the breeding behavior and post-hatching neonatal behavior in the wild are particularly valuable.

On 3 September 1991, a local fisherman found a nest with eggs of an African rock python (*Python sebae*) in Gombe Stream National Park, on the eastern shore of Lake Tanganyika in Tanzania. The female and her eggs were in a burrow on a steep grassy slope about 25 m above the gravel beach of the lake, with a western exposure and sunlight falling on the hole from mid afternoon until sunset. Holes are numerous in slopes at Gombe, and are frequently dug by pangolins. The female python was coiled around her eggs; her length was estimated at 2.75 m. About 20 eggs were deposited 60 cm into the recess of the burrow. It is not known how long the eggs and mother had been present at the time they were first observed.

The eggs hatched on 20 or 21 November, and hatchlings were visible around the entrance to the nest site. The incubation period was thus at least 78 days. I made frequent trips to the nest to observe the behavior and dispersal pattern of the neonates. The maximum number of hatchlings seen on a single trip was 19. Three hatchlings were measured and had an average total length of 57 cm. On the first day the hatchlings were observed, the mother was visible deep within the nest hole; she was not seen again, and it is not known whether she left the site once the eggs hatched or remained nearby.

A strong degree of nest site fidelity was observed in the hatchlings. For the first week after hatching, the hatchlings left the nest hole and basked in pairs or small groups on the hill in a 4 m radius from the hole. They typically left the nest hole as soon as the sun rose above the slope of the hill on which the nest site was located. By late afternoon, the hatchlings reentered their nest hole and appeared to remain there until the following day. When I approached the nest, some of the hatchlings would flee into the hole, while others remained coiled in the sun nearby. Even those hatchlings located up to 4 m away from the hole retreated to it when frightened. When hatchlings were captured and handled, they fled into the nest hole from up to 2 m away immediately upon release; hatchlings that were handled and released more than 2 m away did not return to the nest hole.

On 26 November, the hatchlings began to enter their first skin shed cycle. They continued to bask in the sun each afternoon and use the nest hole as a home base. Beginning on 29 November fewer hatchlings were seen in or near the nest hole, and by 1 December all appeared to have left the site, probably after their first shed. The nest hole was thus used as a shelter for about 10 d, after which the hatchlings dispersed. This hole was apparently not reused as a nest site in 1992 or 1993.

I thank the Tanzanian Commission for Science and Technology (COSTECH) and the office of Tanzania National Parks, and Dr. Jane Goodall for permission to work in Gombe National Park. Financial support was provided by the National Geographic Society and the L.S.B. Leakey Foundation. Harry Greene made helpful comments on the manuscript.

SIPHLOPHIS PULCHER (NCN). **PREY**. Feeding habits of the five recognized species of the neotropical snake genus *Siphlophis* are scarcely documented and the information seems controversial. The widespread *S. cervinus* is nocturnal, terrestrial to semiarboreal, and is reported to prey on birds and lizards (e.g., Duellman 1990; Zimmerman and Rodrigues 1990. *In* Gentry, ed. Four Neotropical Rain Forests. Yale Univ. Press, New Haven, Connecticut, 612 pp.). However, the few substantiated prey items include two species of lizards: *Bachia trisanale*, a fossorial gymnophthalmid (Duellman 1978. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 65:1–349), and *Thecadactylus rapicaudus*, a nocturnal and arboreal gekkonid (Nascimento et al. 1987. Bol. Mus. Para. Emilio Goeldi, sér. Zool. 3:33–65). We are unaware of reliable dietary information on any of the three species of *Siphlophis* from the coastal rain forest of southeastern South America.

Here we report on six instances of *S. pulcher* feeding on squamate prey, and comment on the need to reassess the importance of bird prey in the diet of *S. cervinus*. Specimens of *S. pulcher* were observed in, or came from, the Atlantic Forest of eastern and southeastern Brazil (States of Bahia and São Paulo) during the wet season from October to March in the years 1991 and 1993. Vouchers of snakes and their prey are in the Instituto Butantan, São Paulo (IB 54225), the Museu de História Natural de Campinas, São Paulo (ZUEC 1636, 1659), and the Centro de Pesquisas do Cacau in Itabuna, Bahia (CEPEC 1580, 2376).

One adult *S. pulcher* (SVL = 695 mm; tail = 179 mm; tail tip missing) was found in early morning on 10 October 1991 on the ground within a cacao grove at Ilhéus, Bahia. The snake was swallowing an adult and considerably longer blunt-headed tree snake, *Imantodes cenchoa* (SVL = 770 mm; tail = 348 mm), a nocturnal colubrid (Cunha and Nascimento 1978. Publ. Avuls. Mus. Para. Emilio Goeldi 10:1–218; Duellman 1990, *op. cit.*). We found the remains of an unidentified gekkonid lizard in the gut of the same *S. pulcher* and a recently eaten *Anolis* sp. in the gut of the *Imantodes*. A juvenile *S. pulcher* (SVL = 220 mm; tail = 65 mm), also from a cacao grove at Ilhéus and received March 1993, contained a broken, recently swallowed lizard tail (60 mm) and two lizard eggs (7 x 3 mm), presumably of a gymnophthalmid. An adult *S. pulcher* (80 cm TL) was found on the evening of 15 December 1991 on branches of a fallen tree, 1 m above ground within a secondary forest at Caraguatatuba, São Paulo. Upon capture it disgorged a freshly eaten specimen of the terrestrial gekkonid, *Gymnodactylus darwini*. An adult female *S. pulcher* (SVL = 535 mm; tail = 165 mm; mass = 32 g), caught 1 February 1991 on the ground at Caraguatatuba, contained a whole specimen of the diurnal gymnophthalmid lizard *Placosoma glabellum* (SVL = 60 mm; tail = 55 mm; mass = 3 g) and the tail of a second one in its gut. Another female *S. pulcher* (SVL = 615 mm; tail = 182 mm; mass = 64 g) caught February 1993 in Ubatuba, São Paulo, contained the ubiquitous gekkonid lizard, *Hemidactylus mabouia* (SVL = 60 mm; tail = 90 mm; mass = 5 g). A specimen of *S. pulcher* (65 cm TL), caught at Boracéia, São Paulo and received alive at the Instituto Butantan on 14 January 1991, disgorged the remains of a *Placosoma* sp. (O. A. V. Marques, pers. comm.).

Our observations on *S. pulcher* and literature data on *S. cervinus* indicate that these snakes are nocturnal active foragers searching for prey both on the ground and on vegetation. These snakes feed on inactive diurnal vertebrates (lizards and possibly birds), active nocturnal ones (lizards and snakes), and squamate eggs. The importance of birds in the diet of *Siphlophis* should be reassessed, since reliably documented records indicate squamates as prey. Although Cunha and Nascimento (*op. cit.*) stated that only birds were found in the diet of *S. cervinus*, they failed to mention whether prey were found in only one or a few of the nine snakes they examined. We suspect additional data will support our conclusion that species of *Siphlophis* feed primarily on squamates, a condition found in many if not most pseudoboine snakes.

We thank O. A. V. Marques and G. Puorto for data on the IB specimens and their prey; V. Rodrigues for the Ilhéus adult snake; M. J. Silva for the Ubatuba snake; M. T. Rodrigues for the identification of two *Placosoma* prey; the CNPq and the Fundação Banco do Brasil for financial support.

Submitted by **IVAN SAZIMA**, Departamento de Zoologia, Universidade Estadual de Campinas, 13081-970 Campinas, São Paulo, Brazil, and **ANTÔNIO J. S. ARGÔLO**, Centro de Pesquisas do Cacau, Caixa Postal 7, 45600-000 Itabuna, Bahia, Brazil.

THAMNOPHIS RUFIPUNCTATUS (Narrow-headed Garter Snake). **COLOR** and **SIZE**. Hedges et al. (1989. J. Herpetol. 23:450–455) reported natural, physiological color change to be uncommon in snakes, being known to occur in seven species of insular non-colubroidean snakes and in two species of mainland crotalines. These snakes are terrestrial (eight species) or arboreal (one species).

FIG. 1. *Thamnophis rufipunctatus*, light phase, photographed 1 October at 1500 h.

On 1 October 1988, at 1500 h (air temperature ca. 24°C), a 953 mm female *Thamnophis rufipunctatus* was found lying at the shoreline of the Black River at Buffalo Crossing, Apache Co., Arizona. At time of capture the snake was tan with darker brown spots (Fig. 1). The snake was kept alive overnight in complete darkness. On 2 October, at ca. 1100 h (air temperature ca. 20°C), the snake was taken into direct sunlight and found to be soot colored dorsally, with the darker spots indistinct (Fig. 2). The snake was left in indirect sunlight for two hours but showed no indication of a return to the previous pale coloration, even after subsequent preservation. Conspecifics found in the Black River on 1 October were of the tan phase (three) or dark phase (two).

FIG. 2. *Thamnophis rufipunctatus*, dark phase, photographed 2 October at 1100 h; same specimen as Fig. 1.

This is apparently the first record of both a colubrid, and an aquatic snake, exhibiting physiological color change. This specimen (California Academy of Sciences 186445) exceeds the previously reported maximum length of 86 cm (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co. Boston, Massachusetts. 336 pp.).

Submitted by **JEFF BOUNDY**, Museum of Natural Science, 119 Foster Hall, Louisiana State University, Baton Rouge, Louisiana 70803, USA.

THAMNOPHIS SAURITUS SACKENII (Peninsula Ribbon Snake). **BEHAVIOR**. A female *Thamnophis sauritus sackenii* was observed eating a *Hyla cinerea* 5.72 m up in a red maple tree (*Acer rubrum*). Distress calls by the frog caused us to notice the ribbon snake. The snake was captured after we vigorously shook the tree. As the snake fell the frog escaped from the snake's jaws and hopped away apparently unharmed. The 17.4 g snake (SVL = 41.2 cm) was found at 1720 h on 20 September 1993, in a hammock with sabal palm and live oak canopy. Air temperature was 28–30°C. Rain had fallen 24–72 h earlier. To our knowledge, this is the first report of *Thamnophis sauritus sackenii* foraging in a tree canopy.

We thank Fred Link for tree shaking and Peter May for helpful comments.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 25, number 1.

Cosymbotus platyurus In Florida: Ten Years Of Stasis

At present, Florida is colonized by eight species of geckos (Wilson and Porras 1983, The Ecological Impact of Man on the South Florida Herpetofauna. Univ. Kansas Spec. Publ. 9, Lawrence, 89 pp.; Lawson et al. 1991. Herpetol. Rev. 22:11–12; Meshaka et al. 1994. Herpetol. Rev. 25:80-81). Herein we report an established colony of *Cosymbotus platyurus*, a species new to Florida and the United States, based on a voucher (USNM 244208) collected by us on 7 November 1993 from a colony located in Clearwater, Pinellas County.

This colony is located on a strip mall in downtown Clearwater and has been known to one of us (JL) since 1983. The presence of *C. platyurus* coincided with the opening of a pet shop two years prior to the detection of this colony. The pet shop, still in existence, deals in the exotic reptile trade. From one walk around the mall on the evening of 13 November 1993, we counted 51 individuals (45 adults, 6 hatchlings). The largest adults, presumably males, were consistently found at the tops of the buildings and were extremely wary. Almost all hatchlings were observed <1.5 m above the ground. When dazzled with the flashlight, hatchlings elevated and wriggled their tails.

We found few to no individuals on nearby buildings. This observation, like our census on the main building, was consistent with observations by JL since 1983. Unlike other hemidactylines of Florida, *C. platyurus* has shown little ability to disperse from its original site of introduction. Too little is known about the natural history of this species to explain its poor colonizing ability in this target area. To date, this population of *C. platyurus* represents an end point in the spectrum of successful colonizers. The colony is persistent and healthy but thus far unable to expand from one very localized site.

Submitted by **WALTER E. MESHAKA, JR.**, Archbold Biological Station, P.O. Box 2057, Lake Placid, Florida 33852, USA, and **JOHN LEWIS**, 1312 South Evergreen Avenue, Clearwater, Florida 34616, USA.

Hemidactylus frenatus Established On The Lower Florida Keys

Hemidactylus frenatus is an Old World gecko with a large natural and human-assisted geographic range. In the United States it has flourished in Hawaii, where it was presumably transported on equipment during World War II (McKeown 1978). Here, we report the establishment of *H. frenatus* on Stock Island and Key West, Monroe County, Florida, provide some natural history information from our collections and field observations, and comment on its presence in syntopy with other hemidactylines on the lower keys.

All specimens were collected by the authors and will be deposited in the United States National Museum (USNM). Snout-vent lengths (SVL) of all specimens from this series are given in mm. Ronald I. Crombie kindly identified specimens USNM 217918, 217920, and 217923. Vouchers documenting this discovery are from:

Monroe Co: Stock Island. 21 September 1993. USNM 217933–217935. Immatures, 35, 27, and 30 mm, respectively. USNM 217906. Male, 54 mm. USNM 217907. Female, 47 mm.

Monroe Co: Key West. 23 September 1993. USNM 217918–217919. Males, 53 & 50 mm, respectively. USNM 217920, 217922–217923. Females, 47, 46, and 49 mm, respectively. USNM 217921. Immature, 23 mm.

All four females collected contained four sets of follicles >1.0 mm. Of these, shelled eggs (diameters in parentheses) were found in USNM 217922 (7.4 and 8.6 mm) and USNM 217923 (8.0 and 9.0 mm). Our single collection of series precluded estimation of the egg-laying season. However, *H. frenatus* is known to produce eggs continuously in source areas (Church 1962; R. I. Crombie, pers. comm.). Female *H. frenatus* which mature at 38 mm SVL in Java (Church 1962) could represent the smallest minimum size at maturity of the hemidactyline geckos in Florida (Meshaka 1993; Meshaka et al. 1994b).

No *Hemidactylus frenatus* were found on any of the other keys we visited during this trip. On Stock Island, where we collected five *H. frenatus*, we also collected thirteen *H. mabouia* and observed but failed to collect two *H. garnotii*. On Key West, where we collected six *H. frenatus*, we collected seven *H. mabouia*, three *H. garnotii*, and one *H. turcicus*. Our method of collecting geckos was to not target any particular species in order to be as nonselective as possible. Results of this collecting method yielded proportions of species similar to what we observed.

In our collections, *Hemidactylus mabouia* was the most common hemidactyline gecko throughout the Florida Keys, having replaced *H. turcicus* in Key West (Meshaka et al. 1994a). Indeed, the *H. turcicus* we collected was the only individual seen throughout the Florida Keys during this trip. *H. garnotii*, which was only

recently detected in the Florida Keys (Wilson and Porras 1983), was infrequently seen by us and primarily at opposite ends of the Florida Keys. At present, *H. frenatus* does not yet appear to be established farther north than Stock Island where it was outnumbered more than 2:1 by *H. mabouia* in our collecting effort.

A likely source of the introduction for *Hemidactylus frenatus*, we believe, was a pet shop in Key West which has been in existence for almost twenty years. This store dealt in the exotic reptile trade, including old world species. *H. frenatus* could have reached Key West via transportation on shipments as stowaways from wholesalers in southern Florida. If this is true, further collecting on mainland southern Florida might detect its presence near the airport in Miami and/or at wholesale distributors of reptiles, and place *H. frenatus* on the long list of exotic species established through a weakly restricted exotic wildlife trade.

The rapidly spreading urban habitat of Florida has brought with it an endemic herpetofauna including four hemidactylines. The source for many of these exotic species has been the pet trade. This system has resulted in an unnatural experiment in colonization, niche partitioning, and competition. Among the house geckos, *Hemidactylus frenatus* appears to be the most recent invader and is similar in appearance to its congeners.

The current status of *Hemidactylus frenatus* on the lower keys lends this species well to testing two working hypotheses. First, rapid expansion of *H. frenatus* along the chain of keys would corroborate our suggestion that *H. frenatus*, a proven successful colonizer, is the most recent invader of the hemidactyline geckos on the Florida Keys. Second, replacement of *H. mabouia* by *H. frenatus* in southern Florida will test the hypothesis that, unlike the colonization of anoles in Florida (Wilson and Porras 1983; pers. obs.), ecological overlap on buildings of the four hemidactyline species currently in Florida may be too great to permit a stable coexistence of more than one dominant species at one time.

Range Extensions For Louisiana Amphibians And Reptiles

A survey of recently accessioned amphibian and reptile specimens in the Louisiana State University Museum of Natural Science (LSUMZ) has revealed a number of range extensions, based on comparison with localities depicted on range maps by Dundee and Rossman (1989). Each specimen represents a parish record. Identifications were verified by Douglas A. Rossman or David A. Good.

AMBYSTOMA TALPOIDEUM (Mole Salamander). East Feliciana Par: 4.8 km (by air) S Jackson. 2 April 1993. J. Boundy, J. Slowinski. LSUMZ 55796.

EURYCEA QUADRIDIGITATA (Dwarf Salamander). Tensas Par: 1.6 km S Waterproof. 2 March 1965. L. Wilson, A. Romano. LSUMZ 51827. 1.4 km W Newlight. 16 April 1966. L. Wilson. LSUMZ 43524, 43525.

NECTURUS BEYERI (Gulf Coast Waterdog). Natchitoches Par: Kisatchie Creek, Natchitoches. 24 February 1954. C. Ward. LSUMZ 51953.

NECTURUS MACULOSUS (Mudpuppy). Bienville Par: Saline Bayou at La. Rt. 155 bridge. 5 June 1993. E. DeWalt. LSUMZ 56119.

PLETHODON KISATCHIE (Louisiana Slimy Salamander). Natchitoches Par: 14.4 km W Derry on Red Dirt Road. March 1969. L. Wilson. LSUMZ 28668.

ACRIS CREPITANS (Northern Cricket Frog). West Baton Rouge Par: 17.6 km W Mississippi River on Rt. 190. 15 Feb 1962. F. Hayse. LSUMZ 18023. 4.0 km ENE Rosedale on Rt. 76. 8 March 1968. A. Rekas. LSUMZ 22714, 22717. 7.2 km SSE Arbroth on La. Rt. 415. 30 March 1969. A. Varkey. LSUMZ 50929. 8.0 km (airline) W Brusly. 30 March 1968. J. Cattan. LSUMZ 21004. 8.0 km S Port Allen, 0.8 km W La. Rt. 1. 14 Feb 1990. J. Wilkinson, S. Doody. LSUMZ 49494.

HYLA CHRYSOSCELIS (Cope's Gray Treefrog). Tensas Par: 9.6 km SW jct of Hwy 65 and La. Rt. 128. 2 March 1965. L. Wilson, A. Romano. LSUMZ 51543.

HYLA SQUIRELLA (Squirrel Treefrog). West Baton Rouge Par: Rosedale Road. 7 April 1964. L. Wilson, A. Romano. LSUMZ 51606.

RANA GRYLIO (Pig Frog). Cameron Par: Grand Cheniere. 28 April 1957. S. Russell. LSUMZ 50204.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). Winn Par: Cloud Crossing Recreation Area, WSW Brewsters Mill. 26 April 1969. R. Munz, G. Alvarez III. LSUMZ 50861–50864.

APALONE MUTICA (Smooth Softshell). West Feliciana Par: Mississippi River at mouth of Thompson Creek. 13 September 1982. Connor, Brennan and Boyer. LSUMZ 54377. 4.8 km S Rt. 66 in Bayou Sarah. 23 Aug. 1991. S. Doody. LSUMZ 54239–54246. Thompson Creek at Rt. 61. 7–9 Sept. 1991. S. Doody. LSUMZ 54247–54251.

MACROCLEMYS TEMMINCKII (Alligator Snapping Turtle). Vermilion Par: no further data. LSUMZ 55602.

TERRAPENE CAROLINA (Eastern Box Turtle). St. Bernard Par: jct of La. Rt. 46 and La. Rt. 39. 27 March 1978. Ludvet. LSUMZ

47491. Winn Par: 5.0 km W jct of La. Rt. 505 on La. Rt. 126. 20 May 1973. R. and P. Blaney. LSUMZ 53436, 53437. 13.0 km ESE Calvin on La. Rt. 501. 26 April 1969. W. Eberle, R. Blaney. LSUMZ 23985.

TRACHEMYS SCRIPTA (Slider). Ascension Par: Petite Amite River. 20 April 1975. LSUMZ 47620, 47624, 47635–47639. St. Bernard Par: Chalmette Water Board Road. 2 May 1973. LSUMZ 47621.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). Evangeline Par: between Mamou and Ville Platte. Sept. 1990. J. Fairchild. LSUMZ 49571, 49572.

COLUBER CONSTRICTOR (Racer). Acadia Par: Rayne. 10 April 1993. D. O'Quinn. LSUMZ 55908.

LAMPROPELTIS TRIANGULUM (Milk Snake). La Salle Par: Muddy Bayou, Saline Wildlife Management Area. 26 July 1993. J. Slowinski. LSUMZ 56153.

STORERIA OCCIPITOMACULATA (Redbelly Snake). Iberville Par: 435 Pecan Drive, 6.4 km N St. Gabriel. 19 April 1993. S. Cardif; D. Dittmann. LSUMZ 55882.

MICRURUS FULVIUS (Eastern Coral Snake). Acadia Par: 300 Pinewood Drive, Crowley. Oct. 1993. B. Core. LSUMZ 56314.

County Records For Texas Amphibians And Reptiles

An examination of distribution maps provided by Dixon (1987) has revealed that a number of amphibian and reptile specimens in the Louisiana State University Museum of Natural Science (LSUMZ) collection represent county records. Specimen identifications were verified by either Douglas Rossman, David Good or Joseph Slowinski.

SIREN INTERMEDIA (Lesser Siren). Polk Co: Texas Farm Road 943, 0.7 km NW jct. Texas Farm Road 2798. 24 March 1991. D. A. Good. LSUMZ 53305.

NOTOPHTHALMUS MERIDIONALIS (Black-spotted Newt). Starr Co: Walker Lake. 22 April 1962. F. A. Hayse. LSUMZ 6827–6830.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). Lavaca Co: vicinity of Vienna. 25 Sept. 1978. L. Landry. LSUMZ 39584.

TERRAPENE ORNATA (Ornate Box Turtle). Borden Co: 17.8 km W Gail on Tex. Rt. 180. 20 May 1975. R. M. and P. K. Blaney. LSUMZ 30880.

HOLBROOKIA PROPINQUA (Keeled Earless Lizard). Aransas Co: Rockport City dump. May 1967. L. D. Wilson. LSUMZ 28960, 28974–28979, 29364–29369. Rockport. 23 May 1967. D. E. Hahn. LSUMZ 29639–29651.

EUMECES MULTIVIRGATUS (Many-lined Skink). Irion Co: Barnhart. 1 June 1969. L. D. Wilson. LSUMZ 33828, 33829.

HETERODON NASICUS (Western Hognose Snake). Blanco Co: Edwards Plateau. March 1961. W. Fox. LSUMZ 9275.

LAMPROPELTIS CALLIGASTER (Prairie Kingsnake). Franklin Co: 9.6 km N Mt. Vernon. 27 July 1966. R. Laval. LSUMZ 18763.

LAMPROPELTIS GETULA (Common Kingsnake). Hale Co: Plainview. 4 June 1971. F. Rose. LSUMZ 24691. San Jacinto Co: FM 1725 at San Jacinto River. 16 Sept. 1978. L. Landry. LSUMZ 39585. Uvalde Co: Tex. Rt. 83, 6.4 km S Uvalde. 5 Sept. 1964. R. E. Olson. LSUMZ 10313.

LAMPROPELTIS TRIANGULUM (Milk Snake). Live Oak Co: 20.5 km SSW George West on U.S. Rt. 59. 7 Sept. 1966. L. D. Wilson. LSUMZ 32645.

MASTICOPHIS TAENIATUS (Striped Whipsnake). Lee Co: 8.0 km E Giddings on U.S. Rt. 290. 5 June 1966. H. Hermann. LSUMZ 43562.

PITUOPHIS MELANOLEUCUS (Bullsnake). Willacy Co: 22.4 km S Norias. 18 April 1965. L. D. Wilson. LSUMZ 41906.

REGINA GRAHAMII (Graham's Crayfish Snake). Colorado Co: 3.2 km W Eagle Lake on U.S. Rt. 90. 23 May 1980. L. Landry, W. Shoop. LSUMZ 39550. Lavaca Co: 16 km S Sheridan on FM 2437. 23 May 1980. L. Landry, W. Shoop. LSUMZ 39549.

SONORA SEMIANNULATA (Ground Snake). Jim Hogg Co: 4.8 km W Hebbronville. 18 June 1980. L. Landry, W. Shoop. LSUMZ 39578.

STORERIA DEKAYI (Brown Snake). Starr Co: Roma Los Saenz. 6 Aug. 1968. R. E. Olson. LSUMZ 23502.

TRIMORPHODON BISCUTATUS (Lyre Snake). Jeff Davis Co: 13.0 km W of Valentine. 10 Aug. 1977. J. S. McLean, R. Queen. LSUMZ 34726.

VIRGINIA STRIATULA (Rough Earth Snake). Blanco Co: Blanco River Bluffs. 1 April 1961. D. A. Rossman. LSUMZ 7254. Edwards Plateau. 1 April 1961. W. Fox. LSUMZ 8852.

MICRURUS FULVIUS (Eastern Coral Snake). Sabine Co: between Hemphill and Burkville, around Toledo Bend. 2 Sept. 1973. J. E. McCann. LSUMZ 26886.

SISTRURUS MILIARIUS (Pigmy Rattlesnake). Shelby Co: 5 km W jct. Tex. Rt. 139 and Tex. Rt. 1820 on Tex. Rt. 1820. 1 Sept. 1967. L. D. Wilson. LSUMZ 33877.

Not The Last Picture Show: New Collection Records From Paris, Texas (And Other Places)

Dixon (1987) provided comprehensive distribution maps, by county, of the herpetofauna of Texas. Numerous distribution gaps still exist, and new records are constantly being added. The following specimens were collected on several field trips, although the majority (62%) are from Camp Maxey, near Paris, Lamar County, in northeast Texas. Quadrangle names (in parentheses) refer to the USGS 7.5-minute topographic series for Texas.

Camp Maxey (Pat Mayse Lake East Quadrangle) was a mosaic of small impoundments, wooded stream drainages, marshes, pine-oak and oak-hickory woodlands, and grasslands. As part of a contract between the Texas Parks and Wildlife Department (Texas Natural Heritage Program), and the Texas National Guard, the herpetofauna of Camp Maxey was surveyed during 22–24 June 1993. (Field notes are on file at the Texas Natural Heritage Program.)

ANURA

SCAPHIOPUS COUCHII (Couch's Spadefoot). McCulloch Co: US Rt. 87, 2.6 km E of jct FM 3022 (West Sweden), 31°41'31"N, 99°28'13"W. 15 July 1990. Martin J. Whiting. Verified by James R. Dixon. TCWC 68182.

HYLA CHRYSOSCELIS (Cope's Gray Treefrog). Coryell Co: Mother Neff State Park (Eagle Springs), 31°19'55"N, 97°27'54"W. 9–11 April 1993. Martin J. Whiting and James R. Dixon. Individual was a male vocalizing from a dead branch ca. 1 m above a pond; a recording of the vocalization was verified by James R. Dixon. TCWC 70347. Collected with permit SPR 0290-022 issued to JRD. Lamar Co: Camp Maxey National Guard Training Area (Pat Mayse Lake East), 33°48'43"N, 95°32'03"W. 22–24 June 1993. Martin J. Whiting and Andrew H. Price. Verified by Tod W. Reeder. TNHC 52065–8.

BUFO AMERICANUS CHARLESMITHI (Dwarf American Toad). Lamar Co: Northwest of Pat Mayse State Wildlife Management Area (Pat Mayse Lake West), 33°50'N, 95°42'W. 5 April 1991. James H. Yantis. Verified by David C. Cannatella. TNHC 52102–07.

HYLA CINEREA (Green Treefrog). Lamar Co: Camp Maxey National Guard Training Area (Pat Mayse Lake East), 33°47'24"N, 95°32'38"W. 22–24 June 1993. Martin J. Whiting and Andrew H. Price. Verified by Tod W. Reeder. TNHC 52077.

RANA CLAMITANS CLAMITANS (Bronze Frog). Lamar Co: Camp Maxey National Guard Training Area (Pat Mayse Lake East), 33°47'58"-48'08"N, 95°34'20"-34'44"W. 22–24 June 1993. Martin J. Whiting and Andrew H. Price. Verified by Tod W. Reeder. TNHC 52078–81.

RANA PALUSTRIS (Pickerel Frog). Lamar Co: Camp Maxey National Guard Training Area (Pat Mayse Lake East), 33°48'03"N, 95°34'23"W. 22–24 June 1993. Martin J. Whiting and Andrew H. Price. Verified by Tod W. Reeder. TNHC 52070.

TESTUDINES

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). Taylor Co: Dyess Airforce Base (Abilene West), 32°25'30"N, 99°48'50"W. 7 June 1993. Martin J. Whiting. Verified by James R. Dixon. TCWC 70372. Taylor Co: Summer Hill Road adjoining Double Lazy J. Ranch. 1982. Jack Joy. Verified by Carol K. Malcolm. UTACV R 12830.

STERNOTHERUS ODORATUS (Common Musk Turtle). Lamar Co: Camp Maxey National Guard Training Area (Pat Mayse Lake East), 33°47'22"N, 95°32'38"W. 22–24 June 1993. Martin J. Whiting and Andrew H. Price. Verified by Tod W. Reeder. TNHC 52064 (shell only).

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). Lamar Co: Camp Maxey National Guard Training Area (Pat Mayse Lake East), 33°48'28"N, 95°35'05"W. 22–24 June 1993. Martin J. Whiting and Andrew H. Price. Verified by Tod W. Reeder. TNHC 52063 (shell only).

SERPENTES

THAMNOPHIS PROXIMUS PROXIMUS (Western Ribbon Snake). Lamar Co: Camp Maxey National Guard Training Area (Pat Mayse Lake East), 33°48'07"N, 95°34'43"W (TNHC 52073); 33°47'53"N, 95°34'03"W (TNHC 52082). 22–24 June 1993. Martin J. Whiting and Andrew H. Price. Verified by Tod W. Reeder.

NERODIA RHOMBIFER RHOMBIFER (Diamondback Water Snake). Comanche Co: US Rt. 67 at jct with the Leon River (Proctor), 31°56'25"N, 98°27'32"W. 13 July 1989. Martin J. Whiting. Verified by James R. Dixon. TCWC 68539. Found dead on the road.

BOOK REVIEWS

Herpetology of China, by Er-Mi Zhao and Kraig Adler. 1993. Society for the Study of Amphibians and Reptiles, in cooperation with Chinese Society for the Study of Amphibians and Reptiles. Contributions to Herpetology, Number 10, 522 pp., 48 color plates. Hardcover US$60. Library of Congress Catalogue Number 92-61941. ISBN 0-916984-28-1. Available from Robert D. Aldridge, SSAR Publications Secretary (see inside front cover of this issue of *HR* for address).

This remarkable volume consists of: introduction, history of herpetological studies in China, illustrated keys to Chinese amphibians and reptiles, color plates, annotated checklist, distribution of the Chinese herpetofauna, a gazeteer to localities in the literature on herpetology of China, and various appendices and indices. The first page of each of these sections has a series of labeled rectangles along the margin with the indicator of the particular section in black, a device that facilitates finding a distant section when one gently bends the edges of a large number of pages. Several of the longer sections have tables of contents (referred to as "guides"), which also speed finding particular topics or taxa.

As China, defined here to include Taiwan, has such an enormous geographic reach—18° to 53° N, from sea level (and even depressions below sea level) to the Himalaya Mts of Tibet, from wet forests to deserts—it is not surprising that the known herpetological fauna comprises 661 species (as of mid-1992). The introduction has a table showing the breakdown of the fauna into genera, species, and endemic species along ordinal lines. Frogs constitute the largest group (36% of the total) with snakes (30%) a close second. As a resident of North America, I am impressed by the low number (35) of salamanders. Ignoring the caecilians and crocodilians (with one species each), the relative rates of endemism are: salamanders—80%, frogs—61%, lizards—43%, turtles—35%, and snakes—28%. In absolute terms, endemic frogs almost outnumber all the rest of the orders combined.

The historical account ranges from the time of Confucius to 1992 and covers field and laboratory investigations, as well as published work. Because this analysis has a chronological framework, the authors consider separately the work of foreign and Chinese scientists, first the early Chinese scholars, then the Westerners (mainly European) of the 18th–20th centuries, and then the Chinese of this century. The account of work by Chinese scholars since 1949 is divided along disciplinary lines. Work prior to then, whether by foreigners or Chinese, was essentially in systematics or biogeography. Photographs of the researchers and explorers give this chapter a charm and value that most histories of science lack. As this section covers 66 pages, it is not trivial or superficial.

Illustrated keys to genera constitute the next section. It is rather standard, but clear, and the illustrations useful. After each generic name are given relevant plate numbers (see below) and checklist page numbers. Each of the 48 colored plates consists of five to nine photographs with four of the plates devoted to landscapes distributed across the major biogeographic regions (see below). Forty to 52% of the species, varying with the order, are depicted in the photographs. A very small percentage of the subjects are preserved specimens and a few are reproductions of drawings. The small size of the photographs limit their aesthetic quality, but the majority show general habitus and coloration well enough for the purposes of this book. In fact, several plates confirm my own prejudices: *Pelophryne*(?) *scalpta*—I don't know the proper generic allocation for this bufonid, but it does not look like *Pelophryne*. I have doubted the occurrence of *Rhacophorus reinwardti* in southern China and the photograph intensifies my doubt.

The annotated checklist, the next section, has an introduction that carefully spells out the conventions and arguments used in arriving at decisions. In addition, special cases are dealt with by notes. Synonyms are given for all nominate forms that have Chinese type localities. The authors adopt a conservative taxonomic approach. For example, they do not adopt Dubois's conclusions concerning Chinese species of *Micrixalus* because those forms have not been adequately studied, a reasonable decision even though Dubois is probably correct. Also they note they were unable to use Dubois's recent classification of the Ranidae because their checklist was prepared before the appearance of Dubois's publication; that may be an advantage, in view of the uncertainties that surround some of Dubois's conclusions. This checklist is an important contribution, assembling current taxonomic information on this large fauna in one place and, for herpetologists who do not read Mandarin, making the complete Chinese fauna accessible.

The chapter on biogeography gives the distribution of every species in the fauna according to political provinces and biogeographic regions. There is also a brief geographical description of each of the regions and subregions, including a few comments on the herpetofaunal species most characteristic of each. An outline map labels both biogeographic regions and provinces and is a boon to workers not expert in this part of the world. The utilitarian approach of this book is shown again in the 14-page distributional table, which gives the checklist page number for each species. One minor criticism I would make of this section is the poor legibility of a fold-out, sepia tone map of land forms of China.

As a reviewer of this book, I find it difficult to avoid repetition of the adjective "utilitarian." Consider the section titled "Annotated Bibliography." Although most of its 100 pages are devoted to references cited in the text, it also has five pages of "General References" (categorized by topics, such as natural history and venomous snakes) and 15 pages of "Regional References" sorted by Chinese provinces and adjacent countries. With an eye to easing access to the literature, each citation is given in full including place of publication. All abbreviations are explained at the end of the bibliography.

There are three appendices. The first, on Chinese geographical names, gives Pinyin/Wade-Giles equivalents for provinces and modern equivalents for literature names that have changed. Both of these are significant aids to Westerners dipping into the herpetological literature of China. The second appendix, on procedures for collecting and preserving herps, was written by John E. Simmons, The University of Kansas. Although it is well done, this is the only part of the book that mystifies me. Why is it in this book? The final short (three pages) appendix lists Chinese herpetological journals with dates of publication for volumes and numbers. The concluding index is divided into two sections, one for names of persons and a second for scientific names.

I return to earlier comments. This is a remarkable book. It is packed with current information that in many cases is available only to persons who can read Mandarin; it is, as the authors say, the only comprehensive review of all the herpetological taxa of China; it is organized and presented in a way that makes it easy for a reader to move from section to section as one tries to concentrate on a particular taxon. Although ecology or natural history are not dealt with, those topics were outside the stated purpose of the book (". . . a summary of the current taxonomic status and distribution . . .") and anyway their inclusion would have doubled the size of the work. The book is not cheap—$60—but it is none the less a bargain.

Amphibians and Reptiles of Connecticut and Adjacent Regions, by Michael W. Klemens.1993. State Geological and Natural History Survey of Connecticut Bulletin No. 112 , Hartford, ISBN 0-942081-04-8. xii + 318 pp. 32 color pl. US $39.95 + $3 shipping (cloth). A special price of $25 + $3 shipping is available to qualified libraries. Librarians should contact the Geological and Natural History Survey at the Natural Resources Center, DEP, 165 Capitol Ave., Hartford, Connecticut 06106, USA.

I must begin this review by stating that I would have been much happier if this book had been published before I moved out of Connecticut. *Amphibians and Reptiles of Connecticut and Adjacent Regions* is the first in-depth modern work to come out of the Northeast. There have been several recent books from New England states (DeGraaf and Rudis 1983; Hunter et al. 1992) that provide good natural history information, but these are not based on original research from the states involved. DeKay (1842) and Fowler (1907) are classics for the region, but they are long out of date. Klemens has spent 17 years collecting detailed information on the distribution, habitat, life history and current population status of Connecticut's 45 species of amphibians and reptiles.

The introductory chapters provide detailed background into this long-running study. The "History of Herpetology in Connecticut" includes an interesting sidelight on the loss of Lamson's 1931 manuscript of *The Reptiles of Connecticut* (Lamson 1935). Landscape regions of the state are well described as are the habitat

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology***. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1994

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*
Institutional subscription	$60.00		

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

About the Cover.—The cover illustrations were executed by Jeffrey W. Tamplin, Department of Zoology & Physiology, Louisiana State University, Baton Rouge. Clockwise, from upper left: *Thamnophis exsul* (USNM 166423, holotype: Coahuila); *Thamnophis sumichrasti* (USNM 7079a: Veracruz); *Thamnophis scalaris* (MVZ 144489: Veracruz); *Thamnophis mendax* (LSUMZ 35340: Tamaulipas). Readers interested in the systematics of this group of Mexican garter snakes are referred to the following publication: D. A. Rossman. 1992. Taxonomic status and relationships of the Tamaulipan montane garter snake, *Thamnophis mendax* Walker, 1955. Proc. Louisiana Acad. Sci. 55:1–14.

SSAR BUSINESS

New SSAR Publication

The Society for the Study of Amphibians and Reptiles announces a new publication series, *Herpetological Conservation*, to present information about the preservation and management of amphibians and reptiles. This series will be published about once per year and each issue will concentrate on a single subject. Most often, an issue will consist of a monograph, but proceedings of topical symposia may be considered. Papers submitted for publication should document thoroughly a need for conservation and evaluate and recommend management alternatives.

Herpetological Conservation will be rigorously refereed. Manuscripts submitted for publication should be derived primarily from data or analyses not published previously.

Submit manuscripts or direct inquiries to the editor: *Stephen Corn, National Biological Survey, 4512 McMurry Avenue, Fort Collins, Colorado 80525-3400, USA. Tel. (303) 226-9464, Fax (303) 226-9230, email: CornS@mail.fws.gov.*

Donations Needed For SSAR Symposium

"West Indian Herpetology: A Symposium in Memory of Albert Schwartz," is to be held at the 1994 SSAR/HL meeting. Several of the invited participants living in the West Indies require assistance with travel expenses in order to attend the symposium. Donations are being sought from individuals and institutions to help defray travel costs.

All donations are tax-deductible, and may be made payable to "Zoology Trust—Schwartz Symposium," and mailed to *Dr. Robert Henderson, Milwaukee Public Museum, 800 W. Wells St., Milwaukee, Wisconsin 53233, USA.* All contributors will be acknowledged in the symposium program and in any publications emanating from the symposium.

MEETINGS

Venomous Snakes: Ecology, Evolution And Snakebite

A meeting will be held at the London Zoo on 27-28 April 1995, under the auspices of the Zoological Society of London. Areas covered will be "Ecology," "Evolution, biogeography and systematics," "Molecular evolution," and "Venom and snakebite." Proceedings will be published as part of the "Symposia of the Zoological Society of London Series." Persons interested in further details should contact: *Roger S. Thorpe (Venomous Snake Symposium), School of Biological Sciences, Brambell Building, University College of North Wales, Bangor, Gwynedd LL57 2UW, Wales, UK.*

NEWSNOTES

ASC Publication Announcement

The Association of Systematics Collections has published the report, "Guidelines for Institutional Database Policies," the result of its two-year study and workshop on data sharing and database ethics. The report contains guidelines for natural history institutions housing specimen-based databases which address legal ownership, responsibilities of owners and users, and financial support. In addition the report contains examples of data sharing agreements, presentations from the data sharing workshop, the ASC position on collections use agreements, and references on data sharing and transfer policies. 76 pp., 1993. Copies are available for $12 (including postage) from: *ASC, 730 11th Street, NW, Washington, D.C. 20001-4521, USA. Tel. (202) 347-2850.*

Request For Scientific Literature

Do you have scientific books or journal series that you no longer use and would like to donate for distribution to Cuba? The Association of Systematics Collections (ASC) is developing a program to exchange systematics and biodiversity information between North American institutions and Cuban institutions. Please contact the ASC office with the titles of books, journals, or reports in systematics/biodiversity (especially related to Caribbean biota) that you are willing to donate, and we will arrange to ship the materials to an appropriate institution in Cuba. For more information and to contribute contact: *Elizabeth Hathway, ASC, 730 11th Street, NW, Second Floor, Washington, D. C. 20001-4521, USA. Tel. (202) 347-2850; Fax (202) 347-0072.*

Charles Stearns Grant-In-Aid For Herpetological Research At The California Academy Of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due by 15 October 1994, with notification by 1 December 1994. Grantees are expected to complete their Academy visit by 15 September 1995. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

Missouri Department Of Conservation

Six wildlife research assistant positions will be availablefrom 24 August–2 November 1994 to work on the herpetological study in the Missouri Ozark Forest Ecosystem Project. Workers must be able to identify amphibians and reptiles to species. The wage is $8/hr for a 40-hr week. Housing, utilities, and vehicles are provided. Inquiries to: *Rochelle Renken, Missouri Department of Conservation - Wildlife Research Section, 1110 South College Ave., Columbia, Missouri 65201. Tel. (314) 882-9880. Deadline for receipt of applications is 1 July 1994.*

SSAR/HL Meeting Highlights

Dates: 28 July–1 August 1994
Place: The University of Georgia, Athens, Georgia

Keynote Lecture: "The Evolution of Reptilian Viviparity Revisited," by Richard Shine (University of Sydney).

Forum: "Issues in Conservation: Point-Counterpoint." *Moderator*: Robert Jaeger. *Speakers*: Henry Wilbur and S. Bradley Shaffer.

Symposium: "Field and Behavioral Endocrinology." *Organizer*: Diana Hews. *Participants:* Dale DeNardo, Louis J. Guillette, Tyrone Hayes, Lynne D. Houck, Rosemary Knapp, Robert T. Mason, Mary Mendonça, Catherine Propper, Matthew Rand, and Thane Wibbels.

Symposium: "Interfaces Among Inter-individual Variation, Life Histories, and Population Dynamics of Reptiles and Amphibians." *Organizer:* Arthur E. Dunham. *Participants not yet finalized.*

Symposium: "West Indian Herpetology: A Symposium in Memory of Albert Schwartz." *Organizers:* Robert W. Henderson and Robert Powell. *Participants (tentative)*: Karen Anderson, Karen A. Bjorndal, Alan B. Bolten, Hans E. A. Boos, M. Butler, P. A. Burrowes, Ellen J. Censky, Brian I. Crother, Mark L. Day, C. Kenneth Dodd, Jr., William E. Duellman, Alberto R. Estrada, Richard Franz, Mary Garvin, Carla A. Hass, S. Blair Hedges, Duncan Irschick, Thomas A. Jenssen, Rafael L. Joglar, Hinrich Kaiser, Julian C. Lee, Allen R. Lewis, Jonathan B. Losos, Walter E. Meshaka, Jr., José A. Ottenwalder, Octavio Pérez-Beato, Douglas P. Reagan, Jonathan Roughgarden, Andreas Schubert, Sharoni Shafir, Margaret M. Stewart, Richard Thomas, Roger S. Thorpe, Peter J. Tolson, Daniel S. Townsend, and Peter Vogel.

Colloquium: "Turtle Biogeography and Phylogeography." *Organizer:* Brian Bowen. *Participants:* Eugene S. Gaffney, S. Bradley Shaffer, Scott Davis, Edward O. Moll, Fredric J. Janzen, DeEtte Walker, Sandra Encalada, Peter Dutton, Anna Bass, Arthur Georges, Matthew Ostentoski, Trip Lamb, Anders Rhodin, Eli Stahl.

Herpetological Travelogue Slide Shows: Profusely-illustrated lectures of exotic herps and habitats.

Multimedia Presentations: "Herps of the West," and "Amphibians of the Appalachians," by David Dennis and Eric Juterbock; "Namesakes of North American Amphibians and Reptiles," (new) by Kraig Adler and David Dennis.

Oral and Poster Sessions: Several concurrent sessions each day.

Student Paper Awards: Seibert Prizes (SSAR) to be awarded to the two best student-presented papers at the meeting ($250 first prize, $150 second prize). The Herpetologists' League Award for Graduate Research is for the best student-authored manuscript; winner receives $500 and ten years back issues of *Herpetologica*.

"The Great Reprint Scavenge" (for students only!). Professionals are asked to clear unwanted duplicate reprints out of their offices (and receive free raffle tickets as a "thank you").

Social Activities: Welcoming Social, the SSAR Annual Auction, Barbecue Picnic, Graduate Student Program ("Graduate School: The Greatest Pit-fall Trap of All") & Social, local tours.

Field Trips: Zoo Atlanta, Savannah River Ecology Lab, Highlands Biological Station, Okefenokee Swamp, and Sapelo Island.

Art Exhibit: Featuring art with a herptile focus. $100 cash award for the art work judged the most unique and interesting.

Live Exhibit: Featuring herps of the region. Sponsored by Savannah River Ecology Lab.

Costs: Registration $80 student, $115 regular; $160 late registration fee after 20 June. Lodging at Residence Hall (air-conditioned dorms): $13 person/day (double occupancy) and $19 person/day (single occupancy). Lodging at Georgia Center (meeting location) or local Hotel: $45-$51/day (single occupancy) and $52-$55/day (double occupancy).

Further Details: See December 1993 issue of *Herpetological Review* (pages 117–119). Meeting Announcement/Call for Papers was mailed to all North American members of SSAR and HL in March 1994; it is also available on request from *Amy Edwards, Program Coordinator, Museum of Natural History, University of Georgia, Athens, Georgia 30602, USA (telephone 706-542-4137; FAX 706-542-3920; email AEDWARDS@ZOOKEEPER.ZOO.UGA.EDU).*

LEGISLATION & CONSERVATION ALERT

Call for information on the status of amphibians and reptiles: *This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered herps. We are in need of more information, especially on the State and Province level. Please send pertinent information to the Section Editor.*

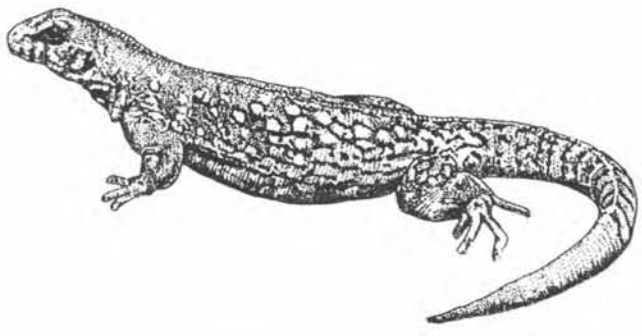
U.S.A.: Department of the Interior: The U.S. Fish and Wildlife Service is soliciting additional information on population trends, levels of trade, and the effect of trade on population status for review in deciding whether to submit a proposal to include the genus *Terrapene* (box turtles) in Appendix II of CITES, while retaining *Terrapene coahuila* in Appendix I. According to USFWS data, 26,817 box turtles were exported from the United States in 1992, and 18,134 were exported in 1993. However, the 1993 data are not yet complete (Federal Register, Vol. 59, No. 18, 27 January 1994). Concerned scientists, conservationists, and citizens should write to: *Dr. Charles W. Dana, Chief, Office of Science Authority, Room 725, Arlington Square Building, U.S. Fish and Wildlife Service, Washington, D.C. 20240, Tel. 703-358-1708, FAX 703-358-2276.* This information was brought to the section editor's attention by: Allen Salzberg, The New York Turtle and Tortoise Society, 163 Amsterdam Avenue, Suite 365, New York, New York 10023, USA.

U.S.A.: Department of the Interior: On 29 November 1993, the U.S. Fish and Wildlife Service proposed the flat-tailed horned lizard (*Phrynosoma mcallii*) as Federally Threatened. The lizard is found in sandy flats and valleys of the western Sonoran Desert in the Coachella Valley through the Imperial Valley, California, and several other areas in México and Arizona. Approximately 40% and 20% of the lizard's habitat has been lost in California and Arizona, respectively. An estimated 95% of the current suitable habitat in California and 35% in Arizona is threatened by continuing human alterations (Endangered Species Tech. Bull. Vol. XIX No. 1, 1994).

The giant garter snake (*Thamnophis gigas*) was listed as Federally Threatened on 20 October 1993. The species occurs in wetland habitats in portions of California's Central Valley. It has been extirpated from two-thirds of its original range (Endangered Species Tech. Bull. Vol. XIX No. 1, 1994).

A proposed rule to list the northern copperbelly watersnake (*Nerodia erythrogaster neglecta*) as Federally Threatened was signed by the Director of the USFWS on 26 July 1993 (Federal Register, Vol. 59, No. 18, 27 January 1994). The current range includes southwestern Indiana and adjacent Illinois and Kentucky, and southern Michigan, northeastern Indiana, and northwestern Ohio. Habitat loss and fragmentation of cypress and willow-buttonbush swamp wetlands are the primary factors threatening the continued existence of the subspecies, however the snake also requires upland wooded hibernation sites above the floodstage line (Federal Register, Vol. 58, No. 158, 18 August 1993).

U.S.A.: Colorado: At the 18 November 1993 meeting of the Colorado Wildlife Commission, the boreal toad (*Bufo boreas boreas*) was uplisted from Special Concern to Endangered. This toad has suffered severe population declines in the past several years. The wood frog (*Rana sylvatica*) was retained as Threatened on the state list. Any person can possess up to 6 of any nongame amphibian or reptile species, except for Threatened or Endangered species. No take is permitted of midget-faded rattlesnakes (*Crotalus viridis concolor*) and massasaugas (*Sistrurus catenatus*).



The snapping turtle (*Chelydra serpentina*) and prairie rattlesnake (*Crotalus viridis viridis*) are considered small game species. At the 13 January 1994 meeting of the Colorado Wildlife Commission, new provisions were adopted for the prairie rattlesnake: season from 15 June – 15 August, bag limit = 3, possession limit = 6. This represents increased restrictions for the take of prairie rattlesnakes, as previously there were no bag limits and the season was open year around. Bullfrogs (*Rana catesbeiana*) and tiger salamanders (*Ambystoma tigrinum*) are also considered game animals, and are covered under fishing regulations. For more information contact: *Colorado Division of Wildlife, 6060 Broadway, Denver, Colorado 80216, USA.* This information was submitted by Lauren J. Livo, 1215 S. Osceola Street, Denver, Colorado 80219, USA.

USA: Federal Memorandum of Understanding: On 25 January 1994 the heads of five federal agencies (Bureau of Land Management, Fish and Wildlife Service, U.S. Forest Service, National Marine Fisheries Service, National Park Service) signed a formal Memorandum of Understanding (MOU) in Arlington, Virginia, whereby they all agreed to cooperatively seek ways to protect the habitats of potentially endangered and threatened species. Species to be targeted include those listed under Category 2 status by the U.S. Fish and Wildlife Service and sensitive species listed by the U.S. Forest Service. A Habitat Conservation Assessment (HCA) will be drafted for each species or group of species. This document describes the species' current status and lists the measures that will be undertaken by the appropriate agency to protect its habitat. Much of the focus of the MOU is on interforest, interregional, and ecosystem approaches to conservation. Species requiring conservation efforts can be protected in more flexible and creative ways than would be required under the Endangered Species Act. Once a HCA has been drafted and a formal Conservation Agreement is signed by the appropriate agencies, the likelihood of that species being listed as endangered or threatened is substantially reduced or eliminated.

The first Conservation Agreement, signed by the heads of the U.S. Fish and Wildlife Service regional office and the George Washington National Forest (GWNF) also on 25 January, is for the Cow Knob salamander (*Plethodon punctatus*). This agreement and its companion HCA restricts or eliminates certain activities, including timber harvesting and off-road vehicles, in a 43,000-acre area on Shenandoah Mountain located on the Virginia and West Virginia state line in the GWNF. This reserve, designated by the U.S. Forest Service as the Shenandoah Mountain Crest Special Interest Area, contains approximately 90% of the known range of *P. punctatus* and a number of rare plant species and communities. A Conservation Team, currently being assembled, will oversee all activities in this area.

This information was submitted by Joseph C. Mitchell, Department of Biology, University of Richmond, Richmond, Virginia 23173, USA.

KURT A. BUHLMANN
SSAR Conservation Committee.

IN MEMORIAM

James Clarence Battersby
1901 – 1993

Mr. J. C. Battersby died at his home in Surrey, England, on 3 December 1993, aged 92. For 44 years he was a valued and efficient custodian of the herpetological collections in the British Museum (Natural History). A Londoner, he lived the early part of his life in Chelsea, close to the Museum.

His museum career began in 1917 when, at the age of 16, he was hired as a laboratory assistant to George Albert Boulenger, the renowned taxonomic herpetologist and naturalist. Under Boulenger's tutelage Jim Battersby absorbed a wide knowledge of the rich and historically valuable herpetological collections and developed sound curatorial methods. Almost to his dying days the care, enhancement and maintenance of these collections remained his overriding concern. He was greatly influenced by his master's tireless energy, intellect, and enormous output of scientific papers, catalogues and books and he was deeply appreciative of the example set for him. The museum's established tradition of providing unstinting assistance to visiting scientists from home and abroad was maintained by Battersby and he quickly learned to cope with the vast number of enquiries that flooded into the Reptile and Amphibian Section from both lay persons and specialists.

Boulenger's aversion to dissecting specimens to study their anatomy rubbed off on Battersby. However, following the arrival in 1923 of a young Cambridge University graduate in biology and chemistry, Hampton Wildman Parker, who took charge of the section, the sanctity of type and other material was disturbed. Soft parts and bones came in for close scrutiny and rather less reliance was placed on painstakingly accumulated data. Jim Battersby's strong sense of duty and allegiance to his head of section ensured his accepting what must initially have been considered by him to be a profanity.

When World War II threatened, plans were drawn up for the type material stored in alcohol to be removed to a place of safety in caves in the chalk hills of Surrey, south of London. Jim Battersby, along with ichthyologists Dr. Ethelwyn Trewavas and Fraser Brunner, played the active part in these arrangements. Later, during the height of the London Blitz when bombs were raining down on and around the museum, Jim Battersby was one of the firefighting team. All too soon army service beckoned and he was conscripted. He served as a driver in the Royal Army Service Corps and saw action, first in the North African campaign, then in Italy.

Shortly after the cessation of hostilities Battersby returned to the Museum. In 1946 he took on the additional task of compiler of the Amphibia and Reptilia part of the *Zoological Record*, a most tedious, time-consuming job necessitating burning the midnight oil and working through lunch hours. Remuneration was extremely poor, varying from £15 to £20 per part per annum but the spin off in keeping abreast of the literature was well worthwhile. After the Amphibia and Reptilia parts were separated in 1953, Battersby continued until 1960 to index the section on Recent reptiles. His gracious wife, Nina, joined him to work part-time in the section, transferring references from the *Zoological Record* to card indexes to the families, genera and species. For this wearisome job, but one extremely valuable to staff and visitors alike, she was paid £80 per annum. It cannot be said that the Battersbys got rich from these supernumerary jobs!

In 1951 I was appointed to fill the vacancy that had existed in the Reptile and Amphibian Section since 1947 when Dr. Parker was promoted to head (officially, Keeper) of the Department of Zoology. Battersby lacked the necessary academic qualifications to become head of the section. It said much for Jim Battersby's forbearance that he accepted with good grace a whippersnapper newly fledged from a university in Scotland, a country with an impoverished herpetofauna consisting of one species of snake, frog and toad, two species of lizard and three species of newt. But harder to bear must have been my total ignorance of herpetology. Fortunately he had his first collecting trip to look forward to and soon after my arrival he went off to Kenya's Northern Frontier Division, leaving me behind with a totally inexperienced, part-time lad; we floundered in his absence, though Dr. Parker's visits to the section helped me find my feet.

On JCB's return after his fruitful expedition all three of us were a lot wiser but to guard against any possibility of egos being upset and discontent Dr. Parker wisely advised that I should give Jim Battersby full control of the snake collections. That tactical move helped establish a good working relationship. However, long after Battersby's retirement I was called upon by the Keeper and the Director to update Parker's little popular book, "Natural History of Snakes." A copy of the new edition presented to JCB was greeted with ridicule. The book was never again referred to. His copy disappeared from his shelves. Thankfully his breezy style and wit returned later and good relations were restored.

Battersby's burden of curatorial duties was so heavy that very little time and opportunity were available for original research. Identifying world-wide collections of reptiles, fetching comparative material from the storerooms, and returning to the shelves all specimens used both by him and visitors to the section, formed a major part of his job. He took such pride in his accurate accessioning and in the well-organized collections that he seemed almost to resent and feel guilty breaking off to study material in depth for his own projects. But his herpetological interests were quite broad geographically, including the West Indies, East Africa, the Middle East, and Nepal. His primary focus was snakes and lizards, and most of his relatively few publications—which were meticulous and detailed—dealt with faunal studies and descriptions of new species. His last publication was a personal and sensitive biography of his master, prepared as an introduction to the reprint of Boulenger's papers on American herpetology, issued in 1971 by the Society for the Study of Amphibians and Reptiles.

Dr. Francis C. Fraser, who succeeded Dr. Parker as Keeper, was most anxious that Battersby should continue in museum service beyond the age of 60. But for years JCB had vowed he would retire at 60 and, true to his word he did, in 1961. He and his wife then moved out of London to Surrey where they lived a very quiet life, apparently utterly content in each other's company and with no hobbies other than reading. Nina's severe stroke came as a cruel blow but even as her physical and mental processes deteriorated he insisted on her being at home where he would look after her. His was a very demanding task that would have quickly drained anyone of a weaker frame and character. As her condition worsened he was forced, reluctantly, to give in and employ nurses to help. He outlived her by five years. They had no children.

A Re-evaluation Of Suffocation As The Cause Of Death During Constriction By Snakes

How do constricting snakes kill their prey? Ditmars (1910:148) probably summarized the knowledge in his day when he stated that "A few large individuals [pythons] are bold enough to retain a coil or two of the body that could crush out a human life. ...All [boids] kill their prey by constriction—squeezing it to death." FitzSimons (1930:23) may have been the first to mention a physiological process (asphyxia) as the cause of death of constricted prey: "The python's object is to crush the body so effectually that the lungs are unable to expand, and death follows quickly from asphyxiation. ...When the python is sufficiently large to constrict its victim efficiently, the prey suffers little or no pain. The unsuspecting creature is seized in the great jaws by their formidable armature of recurved teeth and, almost on the instant, its ribs and lungs are crushed in, death being practically instantaneous." Shortly thereafter, Ditmars (1931:49) concluded that constrictors prevented breathing: "It should also be understood that constriction is not so pronounced that the prey is crushed into an elongated mass and thus rendered easier to swallow. There is little or no change in the form of the animal. It is simply killed by being so squeezed that it is unable to breathe." Although Ditmars' idea may have come from FitzSimons, both appear to have influenced most herpetological books that followed, even to the present day, e.g., "Boas and pythons are constrictors, meaning they kill their prey by suffocation." (Stoops and Wright 1993:39).

It has been pointed out that when a python killed a human being (Chiszar et al. 1993) or when the ratio of prey to snake mass (Greene 1992) is large (K. V. Kardong, A. H. Savitzky, pers. comm.), suffocation rather than circulatory arrest could become a significant factor in death. However, a prey/snake mass ratio greater than one is not common in boids (Greene 1988). Here I argue in favor of circulatory arrest and against suffocation as the cause of death by constriction. The assumption is made that the mass of endothermic prey constricted is less than that of the snake. The implications of the combined use of venom and constriction by some colubrid, elapid and hydrophiid taxa (Shine and Schwaner 1985) are not discussed.

Three terms used in this paper are defined as follows: *Asphyxia*—a lack of oxygen and an excess of carbon dioxide in the body, usually from interruption of breathing; *Circulatory failure*—pump failure of the heart with arrest of the circulation beyond the point of recovery as a result of asystole (noncontraction), electromechanical dissociation (electrocardiographic complexes are present in the absence of cardiac output) or ventricular fibrillation (electrical chaos); *Suffocation*—cessation of external respiration (exchange of oxygen and carbon dioxide across the pulmonary membrane) by preventing ventilation (the movement of air in and out of the lungs) through mechanical restraint of the prey's chest wall. (Although "suffocation" is also used in a broader sense, my definition for this discussion does not include strangulation, upper airway obstruction alone, or interference with internal respiration—the uptake of oxygen and release of carbon dioxide at the cellular level. Webster's Medical Desk Dictionary defines *suffocate* as: "1: to stop the respiration of (as by strangling or asphyxiation) 2: to deprive of oxygen: to die from being unable to breathe." [Pease 1986:688]).

At least 32 other herpetological books state prey death from constriction is the result of suffocation, asphyxiation or prevention of breathing (Alvarez del Toro 1982:148; Auerbach 1987:152; Burton 1991:38; Carr 1963:74; Coborn 1985:13, 1991:43; Cogger 1992:600; Englemann and Obst 1981:34; Frank 1978:70; Gibbons 1977:32; Goin et al. 1978:316; Honders 1975:35; Isenmonger 1968:23; Jackson 1983:14; Lanworn 1972:35; Loveridge 1945:110; Mara 1993:16; Marais 1985:75, 1992:130; Marcus 1981:64; Mattison 1986:82; McFarland et al. 1979:479; Morris and Morris 1965:175; Parker 1963:68; Parker and Grandison 1977:38; Shaw and Campbell 1974:22; Shine 1991:168, 1992:186; Sprawls 1979:112; Stidworthy 1974:45; Stoops and Wright 1992:6; Zug 1993:134). Eight other texts indicate that both suffocation and restriction of heart function play a role (Bellairs 1970:123; Bellairs and Attridge 1975:179; Coborn 1992:45; Mehrtens 1987:18; Minton and Minton 1973:218; Oulahan 1976:42; Schmidt and Inger 1957:176; Stafford 1986:26), and in six the cause of death is not discussed (Broadley 1983; Gans 1975; Halliday and Adler 1987; Lancini 1979; Mushinsky 1987; Porter 1972). One book stated that death resulted from stopping the heart from beating (Crompton 1963:95).

Rochelle and Kardong (1993) reported time to subdue prey by a constricting colubrid snake (*Boiga irregularis*) and in their discussion attributed death to suffocation, citing Bellairs (1970). However, Bellairs (1970) included both ". . . stopping its heart beating and preventing it from breathing," but gave no reference for his statement. Rochelle and Kardong (1993) also stated that constriction can rupture blood vessels or organs within the prey and bring about death, but offered no evidence for that conclusion. Thus the specific physiological changes resulting in death of constricted prey appear to await investigation.

In subduing endothermic prey, constricting snakes coil around the thoracic cage containing the heart and lungs. As the coils tighten, it appears the heart is compressed by the ribs and diaphragm, and the latter stabilized by the abdominal viscera, while the lungs are deflated. The force exerted seems greater than that required for control of struggling prey and the prevention of breathing. Based on physiological principles (Parmley 1991), heart compression results in three events which make constriction efficient in affecting immediate circulatory arrest. (1) The increase in intrathoracic pressure interrupts flow of blood from systemic and pulmonary venous systems into the right and left chambers of the heart, respectively. With lack of venous inflow to the ventricles there can be no arterial outflow to the pulmonary and systemic arterial circulations. (2) Cardiac compression prevents expansion of atria and ventricles so cardiac chambers do not fill during diastole. (3) Following contraction, myocardial fibers cannot lengthen due to external compression and effective contraction of the ventricular wall is not possible.

Thoracic compression results in immediate circulatory arrest followed by failure of cellular respiration of the myocardium (heart muscle) and brainstem. Within seconds the capillary circulation to the major organ systems stops and their cells begin to undergo irreversible metabolic changes. Suffocation should take longer to cause death because arterial blood, albeit desaturated and carrying decreasing amounts of oxygen with time, continues to perfuse the capillaries of the myocardium and brain providing some respiration to their tissues. Although thoracic compression interrupts ventilation (breathing) and suffocation is initiated, it is unlikely the latter is the proximate cause of such a rapid demise.

For suffocation to be the primary cause of death, chest compression must be sufficient to prevent breathing while at the same time have limited effect on cardiac output. Systemic circulation would be normal or elevated and would perfuse tissues for a number of minutes. The decrease in oxygen supply and increase in acidosis would proceed at a slower rate than with circulatory arrest. Death could result from both circulatory failure and suffocation, and admittedly compression effectively decreases residual air in the alveoli of the lungs, accelerating oxygen desaturation of pulmonary blood. However, since little or no blood is circulating through the lungs during constriction, lung deflation and suffocation presumably are not major factors in death of constricted animals.

As endothermic prey, mammals and birds are particularly vulnerable to constriction because their high metabolic rate means lack of oxygen to tissues disrupts cellular function quickly. I simulated constriction in twenty laboratory mice (*Mus musculus*) using digital compression of the thorax. With sustained loss of heart beat and failure to revive serving as endpoints, the mean time to death was 42.0 s (SD ± 4.5). Twelve live-trapped white-throated woodrats (*Neotoma albigula*) succumbed in a mean time of 78.6 s (SD ± 13.9). Rochelle and Kardong (1993) reported similar findings for constriction by brown tree snakes (*Boiga irregularis*) which killed laboratory mice by constriction (and without simultaneous envenomation) in a mean time of 50.5 s (SD ± 18.9) from initial seizure to last muscle twitch. Because reptiles and amphibians often have low resting metabolic rates and rely on anaerobic metabolism for much of their energy requirement, they require less oxygen and lower cardiac output. Thus, ectothermic prey should tolerate tissue hypoxia longer and be less vulnerable to death by constriction.

Historically constriction as a prey-subduing behavior may have appeared during the time when a major component of early snake diet was ectothermic (Greene 1983; Greene and Burghardt 1978) and could have evolved initially as a mechanism to immobilize rather than kill proportionately heavier prey prior to consumption (K. V. Kardong, A. H. Savitzky, pers. comm.). I observed an adult colubrid (*Lampropeltis getula*) immobilize a yearling viperid (*Crotalus atrox*) within several minutes of constriction. The rattlesnake was then eaten without resistance and appeared alive as it was engulfed. A possible physiological explanation for this observation involves the reliance of snakes and most other reptiles on anaerobic metabolism allowing rapid energy input when needed without the high maintenance costs of aerobic metabolism. However, anaerobic energy production is of short duration and consequently muscles fatigue more quickly (Pough 1983). Thus ectothermic prey can be effectively immobilized and consumed by a larger snake after several minutes of nonlethal constriction. Further studies are needed to elucidate the physiology of constriction, utilizing both endothermic and ectothermic prey.

Ditmars was an editor of the *Bulletin of the Antivenin Institute of America* and it seems likely he would have read the following: "The ground-mole is a tough customer; yet, a strong, energetic mole was dead in a few seconds from the time it was seized and enfolded by a 5-foot pine snake. It was neither strangled nor suffocated, and the pine snake is not poisonous. None of the snake's folds were at any time around its head or neck. When the snake uncoiled and began to swallow it the mole's body was not unduly distorted.... The coils are then quickly tightened until the pressure interferes with and finally stops the heart's pulsations, which means, of course, that the victim is dead. The process may be assisted somewhat by the incidental deflation of the victim's lungs, but death is too speedy to be accounted for by this suffocation alone." (McLees 1928:105). The argument was compelling, but the one-page essay was apparently given little credibility. It may have been overlooked by others because of limited distribution. (As an aside, Afranio do Amaral, Editor of the *Bulletin*, added to the bottom of the McLees article, "Note: The Neotropic ophiophagous species, *Pseudoboa cloelia* [= *Clelia clelia*] ("Mussurana"), after coiling around its victim, twists the latter's body in such a way as to disjoint the vertebral column before it attempts to crush the skull.— A. do A.").

In summary, death by constriction is most likely the result of circulatory arrest followed by rapid tissue hypoxia of vital organ systems. Although suffocation occurs simultaneously with circulatory arrest, it is not the proximate cause of death. This hypothesis is based on general physiological principles and awaits controlled testing. In the meantime, "circulatory arrest" is a better bet than "suffocation." It is not simply semantics because physiologically there is a significant difference. Frank McLees figured that out at least 65 years ago, but his ideas had little impact.

Acknowledgements.—I thank H. W. Greene and J. Rodriguez-Robles for encouragement and suggestions on early versions of the manuscript. D. D. Beck, B. E. Dial, J. S. Hunter, K. V. Kardong, S. A. Minton, F. H. Pough, and A. H. Savitzky also made helpful comments.

New Legislation For The Protection And Management Of *Dermatemys mawii* In Belize, Central America

The Central American river turtle *Dermatemys mawii* is a large, highly aquatic, herbivorous, freshwater turtle of the Atlantic drainages of southern Mexico, Belize, and Guatemala (Alvarez del Toro et al. 1979; Iverson 1986; Iverson and Mittermeier 1980). It is the monotypic living representative of the formerly widespread and diverse family Dermatemydidae, which dates from the Jurassic of Europe and the Cretaceous of North America, Europe, and East Asia (Hutchison and Bramble 1981; Iverson and Mittermeier 1980; Romer 1956). Throughout its restricted range *Dermatemys* is intensely persecuted for its meat (Alvarez del Toro et al. 1979; Holman 1964; Lee 1969; Mittermeier 1970, 1971; Moll 1986), which is consumed by rural people and sold in urban markets. Because *Dermatemys* lays its eggs in scattered locations during high water periods of the late rainy season, exploitation of nesting females and their eggs is inconsequential (Polisar 1992). Years of unrestrained exploitation have caused concern about the status of *Dermatemys*, and it is listed on Appendix II of the Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES 1984), as endangered under the provisions of the U.S. Endangered Species Act (Code of Federal Regulations 1987), and as a high priority species in the IUCN Species Survival Commission Action Plan for the Conservation of Tortoises and Freshwater Turtles (IUCN/SSC/TFTSG 1991).

Hunting has virtually eliminated *Dermatemys* from much of its former range in southern Mexico (Vogt, pers. comm.), and the status of the species in Guatemala is unclear. As late as 1984 *Dermatemys* was common to abundant in sparsely populated areas of Belize, but declining where accessible to a harvesting public (Moll 1986). Moll (1986) urged that the remaining relatively intact populations in Belize offered an opportunity to obtain the biological data needed to manage this important species.

That opportunity was seized when the seven villages of the Community Baboon Sanctuary, a grassroots wildlands management project that maintains riparian forest habitat for black howler monkeys (*Alouatta pigra*) (Horwich 1986, 1990; Horwich and Lyon 1988), invited me to study *Dermatemys* in the 32 km section of the Belize River that bisects their sanctuary. The invitation stemmed from concern that local levels of harvest had become unsustainable. Field research began in late 1989 and expanded rapidly, eventually including an additional 54 km of the Belize River, 39 km of tributary systems, an additional five villages, urban market counts, and fieldwork in the Rio Bravo Conservation and Management Area and the Crooked Tree Wildlife Sanctuary. The focal points of the two-year study were reproductive biology and exploitation patterns. The abundance of local cooperation greatly enhanced the collection of data on reproductive cycles, minimum sizes at maturity, nesting and mating seasons, incubation periods, methods of exploitation and marketing, and seasonality, scale, and effects of exploitation. Extended immersed residence in the villages provided an understanding of local perspectives, needs, and customs.

Although exploitation occurred year-round, it peaked during the last two months of the dry season, April and May, when low water levels facilitated captures. In northern Belize there was a strong tradition of having *Dermatemys* (locally called hickatee) for Easter dinner in April. The data showed that repetitious, intense hunting within an area resulted in decreased densities, and lower proportions of adults, particularly adult females. All three methods of hunting (harpoons, nets, and freediving) selected for larger size classes. When the small juveniles that had previously eluded capture matured, they too were collected, providing an illusion of continued abundance in populations that were actually non-

productive and in decline. These dynamics appeared less severe in lightly and intermittently exploited populations. The status of the central Belize River population in the vicinity of the Baboon Sanctuary, and that of other heavily exploited populations, indicated that a more conservative level of harvest was necessary.

The ultimate objective of the project had been to synthesize information on reproductive biology, exploitation patterns, marketing patterns, cultural traditions, and legal and community conservation opportunities, in order to develop pragmatic management recommendations that could function in a rural, undeveloped setting with minimal wildlife law enforcement. Following the analysis those recommendations were delivered to Belize in the form of multiple copies of a lengthy comprehensive report and a short illustrated project summary, seven slide presentations (in urban government and NGO offices, and in village community centers), two radio interviews, and numerous meetings and discussions.

In this country of low human population density, and in the absence of strong enforcement capabilities, restricting the activities of commercial hunters who removed large numbers for profit seemed a feasable initial strategy. Nets and diving tended to result in the removal of larger numbers of animals. Both also tended to be used for commercial hunting. Although numerically more people occasionally harpooned turtles for personal consumption, they removed fewer total turtles. However, there were divers and net men whose take was quite reasonable, making method restrictions innappropriate. A complete ban would be inoperable because noncompliance would be universal. In contrast, a harvest strategy that emphasized the reduction of large scale removal for profit stood some chance of obtaining public support. By allowing continued small scale removals by subsistence hunters, the support of that numerically large constituency might be maintained. It was also essential to recommend some completely closed zones. Those could provide insurance should harvest management prove difficult to implement. Closed zones also had the potential of serving as natural restocking areas.

Some villages were interested in *Dermatemys* conservation, while others were not. Some hunters and villages wanted mechanisms that would enable them to stop what they considered to be excessive and wasteful levels of hunting during the dry season. One example, the village of Freetown Sibun, was interested in establishing legal restrictions for their section of the Sibun River. They were concerned about the decline of turtles in their area, and resentful that non-resident market hunters were removing turtles to sell elsewhere. The village possessed strong leadership and was already close to consensus. Other villages expressed the same concerns, but were less well organized. I worked closely with Freetown Sibun, and they developed a request for local regulations that was submitted to the Ministry of Natural Resources. That document was taken into consideration, as were my detailed recommendations for the remainder of northern Belize, when the Belize Fisheries Department drafted nationwide comprehensive legislation protecting and managing *Dermatemys mawii* in April of 1993 (Statutory Instrument No. 55 of 1993).

This new legislation includes year round possession limits (which should eliminate large scale removals without reducing small scale use), a short closed season (1–31 May), a complete prohibition on the sale and purchase of *Dermatemys*, and a series of protected zones in the major waterways of northern Belize, including the entire Rio Bravo system, a section of the Belize River, a section of the New River Lagoon, Cox and Mucklehany Lagoons, and the lower Sibun River. This includes large and small whitewater rivers, a large clearwater lagoon, darkwater lagoons, brackish lagoons, and an estuary.

Although it is premature to label this a success story, nonetheless it is a positive progress report. Several follow-through activities are advisable. One is continued work with rural communities to increase appreciation of the uniqueness and vulnerability of *Dermatemys*, to assess compliance, and to identify any need for further fine-tuning of the regulations. Although it is essential to ensure compliance in urban meat markets, the substantial trade that has been taking place outside those formal markets will also need to be monitored. Field research on large, spatially dispersed, herbivorous turtles occupying large, deep aquatic habitats can be surprisingly labor intensive and expensive, making one of the most urgent needs difficult to realize due to funding constraints. The densities and population structures of exploited and unexploited sections of rivers should be compared over time. That would provide a true assessment of the efficacy of the new management measures, and might also provide information useful for the management of other turtles in other regions.

Acknowledgments.—Research was funded by NYZS–The Wildlife Conservation Society, Chelonia Institute, Programme for Belize, Lincoln Park Zoo, IFAS International Programs and the Program for Studies in Tropical Conservation at the University of Florida, Manomet Bird Observatory, and Sigma Xi. Support for follow-through work came from the Chelonia Institute, Crystal Channel Foundation, Fossil Rim Foundation, and the Tropical Conservation and Development Program at the University of Florida. Logistical support can be credited to the Community Baboon Sanctuary, Belize Audubon Society, Belize Center for Environmental Studies, Chau Hiix Lodge, Belize Meteorological Service and Hydrology Department, Lighthawk, and British Forces Belize. The Belize Forestry and Fisheries Department issued numerous research permits and assimilated the resulting deluge of information.

R. Horwich and F. Young were instrumental in the start-up. P.C.H. Pritchard, A. Carr III, D. Collins, J. Behler, M. Klemens, the Chelonia Advisory Group of the AAZPA, and the Tortoise and Freshwater Turtle Specialist Group of the Species Survival Commission of IUCN–The World Conservation Union helped keep it going. Scientific advice was provided by J. D. Congdon, M. W. Ewert, J. B. Iverson, K. Bjorndal, D. Moll, J. P. Ross, and R. C. Vogt. F. W. King, L. J. Guillette, Jr., J. F. Eisenberg, and F. Percival supervised the M.S. thesis that the project revolved around. Special gratitude goes to over 75 residents of the villages of rural northern Belize. The significant contributors among them are too numerous to credit individually. Without their assistance, the project simply would not have been possible.

The Proper Spelling And Dates For Certain Names Associated With The Endemic West Indian Genus Of Toads (Amphibia: Bufonidae)

The revival by Pregill (1981) of Fitzinger's (1843:32) nominal genus *Peltophryne*, for the endemic bufonids of the West Indies formerly referred to *Bufo* Laurenti, has received universal acceptance since then (e.g., Duellman 1993; Frost 1985; Powell 1992; Schwartz and Henderson 1991).

However, Schwartz and Henderson (1985:8), contrary to Frost (1985), Powell (1992), Duellman (1993), and most other workers, changed the spelling of the generic name in conformance with the gender of its component words: "We have here amended the spelling of this genus. Since *pelta* and *phryne* are both feminine, the correct spelling is *Peltaphryne*, not *Peltophryne*."

Schwartz and Henderson were not the first to note the etymologically correct spelling (correct as confirmed by Dr. Eckart Schütrumpf, Chair of the University of Colorado Classics Department) of Fitzinger's name, and to change the original spelling accordingly. As early as 1933, the generic index of Schulze et al. (1933:2565) recorded that Cope (1862b:358) first proposed *Peltaphryne* as a substitute for *Peltophryne* in his prescient arrangement of species formerly referred to *Bufo*.

Even that citation, by Schulze et al., was in error, for the name first appeared, without explanation or source citation, in the article describing *P. empusa* (Cope 1862a), immediately preceding the cited article (Cope 1862b). In neither work was the reason for substitution given, but undoubtedly it was on etymological grounds; Cope was well versed in classical Greek and Latin. The first work clearly implied substitution of *Peltaphryne* for *Peltophryne* Fitzinger, even though not explicitly so stated, by citation of "*P. peltocephalus*" (Tschudi), the type species of *Peltophryne* (although Fitzinger cited a subsequent use, by "Duméril and Bibron," rather than the original author of the name *Bufo peltocephalus*). Cope maintained usage of the spelling *Peltaphryne* in 1869, in his description of *P. lemur*. Hence the change from *Peltophryne* to *Peltaphryne* clearly was not an "erroneous subsequent spelling," which has no nomenclatural status.

Peltophryne and *Peltaphryne* are separate, distinct generic names under Art. 56 of the International Code of Zoological Nomenclature (hereinafter referred to as the "Code"): "Even if the difference between two genus-group names is only one letter, these two names are not homonyms." *Peltaphryne* is an "emendation," as defined by Art. 33(b) of the Code, being a "demonstrably intentional change in the original spelling of a name other than a mandatory change," and as such is nomenclaturally occupied.

Unfortunately the change in spelling of *Peltophryne* to *Peltaphryne* is contrary to rules of the Code. As kindly pointed out to us by R. W. Henderson (pers. comm.), Powell (1992:3) explicitly rejected the spelling change on that basis: "The use of *Peltaphryne*, initially by Schwartz and Henderson (1988) [actually 1985] and subsequently in other publications by the same authors, was based on the premise that, as *phryne* is feminine, the adjectival portion of the name should agree in gender (A. Schwartz, pers. comm.). However, the ICZN does not ordain this agreement and I have continued to use the traditional spelling." In reality no part of the generic name is adjectival; both component words (*pelto* and *phryne*) are nouns, and indeed must constitute a noun in the nominative singular in order to conform with rules of the Code (Art. 11(g)).

Although we agree that *Peltaphryne* is invalid, the real basis for rejection of the change in spelling is not failure of gender agreement of parts of the name *Peltophryne* (which may be desirable but is not required by the Code), but is found in Art. 32(c)(ii) of the Code, which explicitly eliminates as inadvertent errors (i.e., those that constitute erroneous original spellings subject to correction) any "incorrect transliteration or latinization and *use of an inappropriate connecting vowel*" (our italics).

Therefore, although Schwartz and Henderson (1985), as well as, presumably, Cope (1862a), were quite correct in holding that the two words from which *Peltophryne* was compounded are nouns of feminine gender, rules of the Code require the connecting vowel chosen by Fitzinger (1843) in coining the name to be retained unchanged regardless of being "inappropriate."

Turning to problems associated with species-group names, the proper endings for *peltocephalus* Tschudi and *longinasus* Stejneger, when transferred to the feminine nominal genus *Peltophryne* from their original masculine nominal genus *Bufo*, require attention. Adjectival species group names change endings to agree with the gender of their generic name when transferred from a genus of one gender to that of a different gender, whereas substantive species-group names (nouns) do not. In neither present case did the author indicate whether the species-group name was proposed as a noun or an adjective, and in both cases it could have been either ("shield-headed," as an adjective, or "shield head," as a noun, for the former; "long-nosed," as an adjective, or "long-nose," as a noun, for the latter). In such cases, Art. 31(b)(i) of the Code applies: "Where the author of a species-group name did not indicate whether he or she regarded it as a noun or as an adjective, and where it may be regarded as either and the evidence of usage [original, or subsequent by the original author] is not decisive, it is to be treated as a noun in apposition to the name of the genus; its spelling [i.e., ending] is not changed if it is combined with a generic name of different gender."

Therefore, under the Code the proper endings for these two names are *P. peltocephalus* and *P. longinasus*.

Another species-group name-change to be considered is Cope's (1862b) etymological correction of *peltocephalus* to *peltacephala*, changing the connecting vowel from the original "o" to an "a." As Schwartz and Thomas (1985:13) noted, "many [subsequent] authors have used the [same] etymologically correct" spelling. However, the rules of the Code that require retention of the original connecting vowel of *Peltophryne* do the same for *B. peltocephalus*.

Therefore, Cope's species-group name *P. peltacephala* (as of 1862b) is an unjustified emendation and objective junior synonym of *P. peltocephalus* (Tschudi).

Finally, while examining the name-changes previously discussed, we noted that the dates of publication of some of the names involved have been commonly cited incorrectly. Although many of the articles appearing in the later pages of the early volumes for given years of the Proceedings of the Academy of Natural Sciences of Philadelphia were actually published the following year, both of Cope's articles of present context (1862a, b) appeared in 1862, not in 1863 as cited by Schwartz and Thomas (1975:11) and Schwartz and Henderson (1988:45; 1991:132) for the description of

P. empusa. Nolan (1913:xiii) recorded that signatures 7–9, pp. 321–404 (which embrace both Cope articles) were "Presented to the Academy meeting, October 28, 1862." Their date of publication is therefore clearly 1862. On the contrary, the description of *P. lemur* Cope (1869) did appear in the year following the 1868 Academy meetings, not in 1868 as commonly cited. The description appeared on p. 311 of the sixth signature of Vol. 20 for 1868, but receipt of the fourth signature (pp. 201–296) was not acknowledged by the Smithsonian Institution until 6 February 1869. Although no dates of receipt are given (Nolan 1913:xiii) for signatures 5 (pp. 297–382) or 6 (pp. 383 *et seq.*), they undoubtedly were not mailed until 1869.

Therefore, the correct date of publication for *Peltaphryne* and *P. empusa* is 1862, not 1863, and for *P. lemur*, 1869, not 1868.

Acknowledgments.—We are much indebted to Dr. Eckart Schütrumpf for linguistic counsel, to R. W. Henderson for help with the literature, and to Prof. Juan A. Rivero for nomenclatural counsel.

Sarcophagid Fly Parasitoidism On Developing Turtle Eggs

The larvae of members of two families of polyphagous dipterans (Phoridae and Sarcophagidae) are known to infest turtle eggs (Mullen et al. 1984; Trauth and Mullen 1990; and Acuña-Mesén and Hanson 1990), although in some cases it is unclear whether the larvae function as scavengers (i.e., feeding on non-developing eggs) or as parasitoids (i.e., predating developing eggs; e.g., Acuña-Mesén and Hanson 1990).

Two species of phorid flies (*Megaselia scalaris* and/or *Puliciphora borinque*) have been found infesting the eggs of the Atlantic green turtle *Chelonia mydas* and the hawksbill *Eretmochelys imbricata* in Costa Rica (Bjorndal et al. 1985; Fowler 1979), the slider turtle *Trachemys scripta* in the Canal Zone of Panama (Moll and Legler 1971), and the painted wood turtle *Rhinoclemmys pulcherrima* in northwestern Costa Rica (Acuña-Mesén and Hanson 1990).

Three genera of sarcophagid flies are known to attack the flexible-shelled eggs of turtles. The genera *Phrosinella* and *Eusenotaynia* are known to infest the eggs of the leatherback (*Dermochelys coriacea*) and the Pacific ridley (*Lepidochelys olivacea*) (Andrade et al. 1992). In addition, the genus *Eumacronychia* infests the eggs of the Pacific green turtle *Chelonia mydas* (= *C. agassizii* of some authors) along the coast of southwestern México (Lopes 1982; López Barbosa 1989). Furthermore, the larvae of unidentified (apparently sarcophagid) flies have been recorded as infesting the rigid-shelled eggs of the softshell turtle *Apalone mutica* in Illinois (Muller 1921) and the pliable eggs of the diamondback terrapin *Malaclemys terrapin* along the east coast of the the United States (Aldrich 1916) and the Pacific ridley in El Salvador (Acuña-Mesén and Hanson 1990). We here report the first confirmed infestation of eggs of a non-marine turtle (the eastern box turtle, *Terrapene carolina*) in Georgia by larvae of the genus *Eumacronychia*.

The junior author has maintained an outdoor captive colony of *Terrapene carolina major* (originally from near Port St. Joe, Gulf County, Florida) in Atlanta, Georgia for 12 yrs. Five females nested during late evening in late May and early June of 1991 and their flexible-shelled eggs were removed by 0900 h the next morning for incubation together at room temperature in a peat moss-vermiculite substrate in a tightly covered aquarium. After about thirty days incubation one to two eggs of each clutch appeared indented (i.e., were no longer turgid) and were removed to another container since they were thought to have ceased development. However, over the next several days adult flies were observed emerging from the dimpled eggs through a single, small oval hole (apparently chewed by the larvae) through each egg shell. This characteristic exit hole had also been observed in occasional eggs in nests left in the ground.

Because infertility rates had previously never been as high as 1 to 2 eggs per clutch, and because eggs did not dimple until a month after deposition, it was assumed that the flies were attacking fertile, developing eggs (i.e., they were predators rather than scavengers). Neither the flexible-shelled eggs of map turtles (*Graptemys*) and chicken turtles (*Deirochelys*) nor the rigid-shelled eggs of tortoises (*Testudo*) nesting in the same enclosure were ever found to be infested (in the ground or in the incubator).

Emerging flies were photographed, collected, pinned or liquid preserved, identified by Dr. Robert Hall, and deposited in Atlanta's Fernbank Science Center collection (FSC 92.28.1-4, specimens, and 92.29.1-2, kodachromes of emerging flies). The flies were identified as *Eumacronychia sternalis*, which is very similar to *E. nigricornis*, and previously reported to attack the flexible-shelled eggs of the lizard *Sceloporus undulatus* in the southeastern United States (Trauth and Mullen 1990).

Given that this genus of sarcophagid fly is now known as a parasitoid of the eggs of turtles from southwestern México to central Georgia, and of lizard eggs from Arkansas to Alabama, its

role as a predator on flexible-shelled reptile eggs across North America is probably much more significant than currently realized. Whether the larvae are capable of entering rigid-shelled turtle eggs through their pores (as phorid flies are known to do; Acuña-Mesén and Hanson 1990) remains unknown.

Acknowledgments.—We thank Robert Hall of the University of Missouri for identifying the specimens, and Fred Sherberger of the FSC for facilitating that identification and cataloging the material. Karen Bjorndal provided pertinent literature.

Illustrations Wanted For HR

The editorial staff is looking for high quality illustrations of herpetological subjects for possible publication in *Herpetological Review*. Original drawings should be of a scale that would permit reduction to approximately 30 x 90 mm or smaller. Of particular interest are drawings of material for which locality data or museum catalogue numbers are available; this information should be included with the drawings. Original art (or photocopies) should be packaged to ensure safe delivery and sent to the Editor (address on inside front cover).

The Diet Of Kraits (Elapidae: *Bungarus*)

While X-raying snakes of the Asiatic elapid genus *Bungarus*, commonly known as "kraits," in the course of a phylogenetic study of the genus, I noticed that several individuals of some of the rarer species contained potentially identifiable stomach contents. Considering it useful to publish these records, I dissected the specimens and identified the remains. I decided that a report of these records would be more useful if combined with a summary of all available published information on krait diet. Consequently, I exhaustively searched the herpetological literature for information on krait diet. Diet records for captive kraits were disallowed as probably not accurately reflecting diet in the wild. The present note summarizes the results of the literature search together with the results of my own dissections. In all, dietary information is presented for 112 individuals in nine of the 13 currently recognized species of *Bungarus* (Golay 1985). The individual records are presented in the Appendix and a summary of the records is given in Table 1.

As Table 1 demonstrates, kraits are largely ophiophagous, but some species are more ophiophagous than others. Of the four species represented in the Appendix by at least 15 individuals, *B. ceylonicus* was the most ophiophagous with 90% of the individuals (18/20) containing snake remains. The proportion of individual kraits containing snakes in the other three well-represented species was as follows: *B. fasciatus*, 80% (12/15); *B. caeruleus*, 66% (19/29); and *B. multicinctus*, 34% (13/38). The large proportion of fish and semiaquatic snakes (*Enhydris*) in the diet of *B. multicinctus* from Taiwan was attributed by Mao (1970) to that species' preference for habitats near water. Mao stated that while smaller *B. multicinctus* preferred fish, larger kraits preferred snakes.

Acknowledgments.—I thank the following individuals for allowing me to examine the stomach contents of kraits in their care: C. McCarthy, British Museum of Natural History (BMNH), and K. de Queiroz, T. Fritts, R. Heyer, R. McDiarmid, and G. Zug, National Museum of Natural History (USNM). This study was completed while I was a postdoctoral fellow at the National Museum of Natural History. I thank R. McDiarmid and G. Zug of that institution for their support and assistance. M. Carleton and A. Wynn provided identifications of stomach contents. J. Boundy, D. Good, and D. Rossman read the manuscript and made valuable suggestions for improvement.

APPENDIX

The diet records are presented below, organized by species of krait. Each numbered record represents an individual krait. The identifications of the diet items are preceded by whatever information (sex [F = female, M = male], length, and institutional number) was available on the krait and followed, in parentheses, by whatever information (sex, length, and institutional number) was available on the prey item. Prey items are presented exactly as they were described in the original reference. In situations where only a common name was given or the nomenclature for a taxon has changed, the most likely modern scientific name is presented whenever possible in square brackets immediately following the diet item. Non-amphibian and non-reptilian taxa likely to be unfamiliar to herpetologists are identified in square brackets. Each record ends with the reference.

Bungarus bungaroides.—(1) spotted viper [*Echis*], Shaw and Shebbeare (1930); (2) M, 810 mm, BMNH 80.11.10.140, *Trachischium fuscum* (410 mm, USNM 323255), this study.

B. caeruleus.—(1) F, 806 mm, *Lycodon aulicus* (464 mm), Wall (1904); (2) M, 597 mm, frog, Wall (1907); (3) M, 1067 mm, frog, Wall (1907); (4) M, 565 mm, young *Varanus flavescens*, Wall (1907); (5) M, 1168 mm, *Bufo andersonii*, Wall (1907); (6) F, 927 mm, musk rat, *Crocidura caeruleus*, Wall (1907); (7) F, 343 mm, *Typhlops braminus* [*Ramphotyphlops braminus*] (95 mm), Wall (1907); (8) M, 334 mm, *Typhlops braminus* [*Ramphotyphlops braminus*] (121 mm), Wall (1907); (9) F, 349 mm, *Typhlops braminus* [*Ramphotyphlops braminus*] (57 mm), Wall (1907); (10) M, 368 mm, two small *Typhlops braminus* [*Ramphotyphlops braminus*], small frog, Wall (1907); (11) M, 330 mm, *Typhlops braminus* [*Ramphotyphlops braminus*], Wall (1907); (12) 349 mm, small mammal, Wall (1907); (13) M, 864 mm, *Bufo andersonii*, Wall (1907); (14) M, 927 mm, mammal, Wall (1907); (15) M, 1219 mm, *Bungarus walli* [*B. sindanus*], Wall (1907); (16) M, 819 mm, six young mice, Wall (1907); (17) F, 597 mm, two *Typhlops braminus* [*Ramphotyphlops braminus*] (105 and 133 mm), Wall (1907); (18) 806 mm, *Lycodon aulicus* (464 mm), Wall (1905); (19) toad, Minton (1966); (20) unidentified snake, Minton (1966); (21) 610 mm, *Dipsas gokool* [*Boiga gokool*] (851 mm), Traill (1895); (22) *Zamensis mucosus* [*Ptyas mucosus*], Phipson (1895); (23) rat snake, Ferguson (1895); (24) 787 mm, *Dipsadomorphus trigonatus* [*Boiga trigonata*] (978 mm), Smith (1910); (25-27) *Typhlops fletcheri* [*Ramphotyphlops braminus*], Wall (1919); (28) 1181 mm, *Bungarus*

caeruleus (991 mm), Smith (1914); (29) M, 1230 mm, *Bungarus caeruleus* (F, 980 mm), Dattatri (1984).

B. candidus.—(1) F, 1050 mm, USNM 142422, 3 tail fragments of an unidentified scincid lizard, this study.

B. ceylonicus.—(1) M?, 432 mm, *Aspidura guentheri*, Wall (1921a); (2) M?, 482 mm, *Aspidura guentheri*, Wall (1921a); (3) F?, 425 mm, *Acontias burtoni* [*Nessia burtoni*], Wall (1921a); (4) M, 445 mm, *Aspidura guentheri*, Wall (1921a); (5) 548 mm, *Aspidura guentheri*, Wall (1923); (6-7) *Rhinophis drummondhayi*, Wall (1921b); (8) mammal, Wall (1921b); (9) F, 706 mm, 2 *Aspidura guentheri* (87 and 112 mm), Wall (1924); (10) M, 258 mm, *Aspidura guentheri* (137 mm), Wall (1924); (11) F, 694 mm, 2 *Aspidura guentheri* (100 and 137 mm), Wall (1924); (12) M, 676 mm, *Typhlops braminus* [*Ramphotyphlops braminus*], Wall (1924); (13) F, 564 mm, *Typhlops braminus* [*Ramphotyphlops braminus*], Wall (1924); (14) 500 mm, *Aspidura guentheri*, Wall (1924); (15) 256 mm, *Aspidura guentheri*, Wall (1924); (16) 275 mm, *Typhlops braminus* [*Ramphotyphlops braminus*], Wall (1924); (17) F?, 628 mm, *Aspidura guentheri* (150 mm), Wall (1924); (18) 289 mm, *Aspidura guentheri*, Wall (1924); (19) uropeltides [uropeltid], Günther (1864); (20) 812 mm, *Dipsadomorphus ceylonicus* [*Boiga ceylonicus*] (861 mm), Phillips (1929). Note: De Silva (1987) reported that an unspecified number of *B. ceylonicus* contained *Rhinophis trevelyana*. Because the number of individuals was not specified, this information is not contained in Table 1.

B. fasciatus.—(1) F, 1257 mm, *Tropidonotus stolatus* [*Amphiesma stolata*] (546 mm), Wall (1910); (2) *Zamensis mucosus* [*Ptyas mucosus*], Wall (1910); (3) M, 1346 mm, unidentified snake and *Zamensis korros* [*Ptyas mucosus*] (1283 mm), Wall (1910); (4) M, 1518 mm, 5 snake eggs, Wall (1910); (5) F, 921 mm, unidentified snake and unidentified fish, Wall (1910); (6) M, 1232 mm, unidentified snake, Wall (1910); (7) *Mabuya multifasciata*, Wall (1910); (8) chicken eggs, Shaw and Shebbeare (1930); (9) 1524 mm, *Tropidonotus piscator* [*Xenochrophis piscator*] (762 mm), Evans (1904); (10) 946 mm, grass snake (838 mm), Primrose (1899); (11) 1560 mm, *Xenochrophis piscator* (300 mm), Biswas (1984); (12) BMNH 1956.1.13.9, *Hypsirhina* sp. [*Enhydris*], catalogue of the British Museum of Natural History (unpublished); (13) M, 1405 mm, *Cylindrophis*, Bergman (1962); (14) 1497 mm, *Homalopsis*, Bergman (1962); (15) F, 1314 mm, *Natrix vittata* [*Xenochrophis vittatus*], Bergman (1962); (16) 800 mm, *Xenochrophis piscator*, Saint Girons (1972).

B. flaviceps.—(1) *Trimeresurus albolabris*, Campden-Main (1970); (2) *Ahaetulla*, Campden-Main (1970); (3) M, USNM 51656, unidentified snake, this study.

B. lividus.—(1) M, 700 mm, BMNH 1936.2.3.11, *Ramphotyphlops braminus* (136 mm) and 1 unidentified scolecophidian, this study; (2) M, 835 mm, BMNH 1936.2.3.10, 3 rodents of the genus *Mus*, this study. Note: this last record is apparently the same as reported by Barker (1936). Barker, however, incorrectly described the mammals as "three young shrews."

B. multicinctus.—(1-10) *Misgurnus anguillicaudatus* [cobitid fish], Mao (1970); (11-24) *Fluta alba* [symbranchid fish], Mao (1970); (25-33) *Enhydris plumbea*, Mao (1970); (34) *Bungarus multicinctus*, Mao (1970); (35) snake, Mao (1970); (36) *Eumeces chinensis*, Mao (1970); (37) *Amblycephalus moellendorffi* [*Pareas margaritophorus*], Pope (1935); (38) snake, Pope (1935).

B. niger.—(1) yellow-bellied roughside [Colubridae], Shaw and Shebbeare (1930).

POINTS OF VIEW

Systematics And Subjectivity: The Phylogeny And Classification Of Iguanian Lizards Revisited*

In 1989, Frost and Etheridge published a cladistic reanalysis of relationships among iguanian lizards along with a new taxonomy of the group. Lazell (1992) attacked this work, questioning its methods and most of all its utility, to which Frost and Etheridge (1993) have recently replied. The latter two papers represent antipodal approaches to systematics generally and iguanian systematics specifically. Because some of my work (Schwenk 1988) has been used to support both points of view and since I, like many herpetologists who work on squamates, have a vested interest in seeing these issues resolved, it seems reasonable for me to explore, and hopefully clarify, the nature of the disagreement.

First, it is worth pointing out that in systematics one is dealing with three overlapping issues: (i) phylogeny reconstruction (identification of evolutionary entities); (ii) classification (what entities are to be named); and (iii) rules of nomenclature (how the entities are to be named). The distinctions among them are at once obvious and complex. Some of the complexity stems from the fact that there are competing schools of thought for each of the three subdisciplines. For example, some traditional systematists ("evolutionary" or "synthetic" taxonomists) have conceded that cladistic methodology is best for character analysis and phylogeny reconstruction, but adopt a non-cladistic approach to classification by promoting paraphyletic taxa in their formal classifications (e.g., a "Reptilia" that excludes birds) in order to highlight subjective degrees of phenotypic difference (Mayr 1981; Mayr and Ashlock 1991). Cladists, on the other hand, insist on classifications based on monophyly (evolutionary entities), but at the same time have heretofore accepted rules of nomenclature based on the non-evolutionary system of Linnean categorical ranks (de Queiroz and Gauthier 1990, 1992, 1994). In his general broadside against the Frost and Etheridge (1989) paper, Lazell (1992) has muddled these three different issues, possibly throwing the baby out with the bath water. A fruitful approach might be to consider iguanian systematics generally, and the Frost and Etheridge (1989) study specifically, in light of these separate issues.

Phylogeny Reconstruction

Evolution *is* the unifying principle of biology and, as Frost and Etheridge (1993) pointed out, each lineage has an evolutionary history (phylogeny) that exists whether or not we attempt to discern it, or whether or not we do so accurately. There is now an overwhelming consensus among biologists that phylogeny reconstruction is central to virtually all aspects of comparative, evolutionary biology (Brooks and McLennan 1991; Harvey and Pagel 1991; Lauder 1981, to name only a few). Therefore, phylogeny reconstruction is not only an end in itself, but is the necessary starting point for many evolutionary questions. Seen in this light, any rigorous attempt to reconstruct phylogeny is laudable. Therefore, Lazell's (1992:109) initial question of "why—what good does it do" indicates a failure to appreciate the fundamental importance of Frost and Etheridge's (1989) attempt to reconstruct the phylogeny of Iguania and that the fragmentation of the traditional family Iguanidae into several, less inclusive taxa follows directly from this attempt. Therefore, we need to separate the attempt to delimit monophyletic groups from the taxonomic decisions based on the results. My sense is that Lazell (1992) (and possibly other herpetologists) is so upset by Frost and Etheridge's

(1989) *taxonomy*, that he fails to recognize the service they have done by tackling the phylogeny of an historically refractory group. The identification of monophyletic groups, no matter how unresolved the relationships among them, can only be applauded.

In terms of methodology, I have already pointed out that even so steadfast a supporter of "evolutionary taxonomy" as Ernst Mayr has capitulated on the point of phylogeny reconstruction. The recognition that phylogeny must be inferred from synapomorphy (shared derived features; Hennig 1966) is almost universally accepted by practicing systematists, as Frost and Etheridge (1993) have pointed out. Lazell's (1992) use of "gestalt" for "grouping" species is truly anachronistic and can no longer be abided. Certainly gestalt is useful in field identification, but it is anathema to phylogeny reconstruction. There are countless examples to illustrate this. I conclude that Lazell's (1992) criticism of Frost and Etheridge's (1989) cladistic approach is without basis.

What about his criticism of their characters? Character analysis is the soft underbelly of all systematic studies and is always vulnerable to attack. Cladists may be paying the price for years of published polemics that touted the new systematic methodology as an "objective" science. The heavy reliance of cladistics on computer analysis and its associated jargon has done little to diminish this perception. However, relative to previous methods, there is certainly truth to cladists' claims of rigor. Nonetheless, *a computer analysis is only as good as its character analysis*. And at the heart of any character analysis is investigator subjectivity. Subjectivity is perhaps most apparent at the earliest stages of the analysis: what *is* a character? Most of Lazell's (1992) criticisms fall into this category. We can rarely identify with certainty a single, heritable unit that could reliably be called a character. Such a unit might be atomized into three putatively independent bits of morphology (characters) by the investigator such that a particular hypothesis of relationship is three times falsely strengthened (we have more confidence in a clade supported by three characters than in one supported by a single character). The opposite is also true (one "character" might actually represent three independent bits). In the face of no opposing evidence, we assume that characters are independent and hope that, in any case, enough "good" characters will outweigh such hidden redundancy. Since we cannot judge the quality of a character (i.e., its "phylogenetic signal") except in light of a phylogeny, we can never test our assumptions directly, only indirectly by their congruence with other character sets.

I digress to this extent because I believe that we have made too much of objectivity in systematic analyses. Character analysis, and therefore systematics, will *always* be subjective to some extent. I think that workers such as Lazell (1992) react to the *impression* of objectivity projected by some cladistic studies. Lazell (1992) is right to nit-pick because it is only through a truly thorough understanding of the morphology and all its manifestations that meaningful character analysis is possible. Frost and Etheridge (1993) concede that some of their characters might be more variable than initially described, although they dispute most of Lazell's (1992) specifics. They also agree with the need for rigorous character analysis. In any case, I believe that this is the most constructive plane on which to base criticism, because controversy in the realm of characters, first, is usually resolvable and second, generates greater breadth and depth of knowledge of the phenotype and therefore can only advance our understanding. The key point then, is not that character analysis is an objective process, but that the *reporting of the character analysis is explicit so that dispute is possible!* Thorough character description, description of multiple character states, the rationale for their attribution as plesiomorphic or apomorphic, and representation of the distribution of the states among all salient taxa are all hallmarks of cladistic studies, including Frost and Etheridge (1989). Gestalt cannot accomplish this level of analytical rigor because it cannot be replicated among investigators. The mere fact that Lazell (1992) *is able* to dispute Frost and Etheridge's (1989) character analysis is a testament to the power of their study. While there might be room for disagreement regarding particulars of Frost and Etheridge's (1989) characters, Lazell (1992) is unfair in his wholesale rejection of their study. It would be more useful to see him re-score their characters in a manner consistent with his own interpretation of the morphology, add a few additional characters, justify his decisions with sufficient information (so that others might dispute *him*) and redo the analysis. Then we might have the basis for a real controversy. Until then, we have only an expression of his dissatisfaction.

Finally, Lazell's (1992) accusation of unreasonable emphasis by Frost and Etheridge (1989) on some characters (regarded, without support, by Lazell as trivial) and not others is thought-provoking, but as pointed out by Frost and Etheridge (1993), there is a vast literature, unacknowledged by Lazell (1992), on the pros and cons of character weighting, a controversy that continues to the present moment. Evolutionary taxonomists have long relied on "key characters," (a form of weighting), but one person's key character is another's trivial one. Arguments can be made against any weighting scheme, and it is perfectly reasonable that Frost and Etheridge (1989) did not judge the merit of their characters *a priori*.

The irony is that Frost and Etheridge (1989) and Lazell (1992) have arrived at remarkably similar conclusions about the *phylogeny* of iguanians (so far as we know it): the chameleons form an undoubted monophyletic group; there is a second "group" of non-chameleon taxa that comprises several recognizable (putatively monophyletic) subgroups, some traditionally "iguanid," others traditionally "agamid," the relationships among which are mostly unresolved. The apparent point of disagreement is that Lazell (1992) argues (but does not support) that the non-chameleon taxa form a monophyletic group, whereas Frost and Etheridge (1989) disallow this possibility, suggesting that some subgroups (traditional agamid taxa) are likely to be more closely related to chameleons than to other subgroups, and further point out that there is no evidence to support the collective monophyly of the remaining subgroups. In fact, even this difference fades upon scrutiny: Lazell (1992) uses the word "monophyly" (with reference to his "Iguanidae") in the traditional sense that includes the cladistic notion of paraphyly (Lazell 1992:109). As such, he allows that his "Iguanidae" may, indeed, be paraphyletic, as Frost and Etheridge (1989; 1993) suggest. Therefore, in terms of phylogenetic conclusions (if not the methods used to arrive at them), the differences between Lazell (1992) and Frost and Etheridge (1989) are trivial. Given this similarity, controversy largely reduces to what to do with the putative, monophyletic taxa once we have them. In other words, we have identified the evolutionary units, now what and how are we to name them?

Classification

For Lazell (1992), the crucial aspect of a classification is its utility "for highly communicable information about *easily identified groups*" (Lazell 1992:111; italics added). This view, as compared to that of Frost and Etheridge (1989, 1993) represents a fundamental schism regarding the *nature* of the entities to be named—the basis of classification. For Frost and Etheridge (and cladists, generally), the entities to be named must be "recovered evolutionary units," monophyletic in the strict sense. For Lazell, they are phenotypically distinct groups, easy to tell apart. Some of the members of Lazell's group might be more closely related, in an evolutionary sense, to another group (i.e., paraphyletic) so long as the group is not composed of two or more separate lineages (i.e., polyphyletic). Therefore, Lazell (1992) names as a formal taxon his "Iguanidae" in full knowledge that some of its members may be more closely related to his "Chamaeleonidae" than to other members of the "Iguanidae." He bases this classification largely on "gestalt" and argues that it is more useful to him as a field biologist.

I fully accept Lazell's (1992) cry for "utility" in classification, but

like Frost and Etheridge (1993), I cannot agree that utility is better served by a classification that obscures evolutionary history. While I concede that phenotypically uniform groups communicate something, what they communicate is only sensible in light of evolutionary history. As such, concepts such as evolutionary stasis, convergence, parallelism, adaptation, etc., arise from knowing how phenotypic traits are distributed across the phylogeny. Lazell's (1992) classification cannot accomplish this level of communication. While his subjective classification is of use to him in his individual efforts, it is less likely to be of use to another comparative biologist than is a cladistic classification representing accurately the evolutionary history of Iguania. These arguments are now old. Cladists have long suggested that traditional, paraphyletic classifications could lead to erroneous evolutionary generalizations owing to their inaccurate representation of phylogeny. This fear has been realized, for example, very close to home in the literature on squamate sensory modes, in which false evolutionary conclusions followed directly on Camp's (1923) paraphyletic classification of the group (Schwenk 1994).

In sum, Lazell (1992) argues that phenotypically uniform, easily identifiable groups are the most useful for recognition as formal taxa in classification, even though such taxa might not represent evolutionary history accurately, or may, at best, obscure it. Frost and Etheridge (1989, 1993) embrace cladistic doctrine which eschews the naming of paraphyletic taxa and therefore name only cladistically determined, monophyletic (in the strict sense) groups. They argue that a classification reflecting evolutionary history is the most useful. I concur with the latter view and point out that a cladistic classification is arguably of use to the greatest number of comparative biologists, is certainly the least ambiguous, and is demonstrably the least prone to evolutionary misdirection.

Nomenclature

It seems likely that many herpetologists will accept cladistic practices as thus far described but are, nonetheless, unhappy with Frost and Etheridge's (1989) taxonomy. This taxonomy is radical not because of the evolutionary entities (monophyletic units) identified, nor because of Frost and Etheridge's (1989) philosophy about which entities are to be named (which, after all, is standard practice; Frost and Etheridge 1993), but mostly because of the particular names chosen to represent the taxa and their elevation to family status. However, the names and family status follow directly from Frost and Etheridge's (1989) interpretation of the rules of nomenclature, as outlined by the International Code of Zoological Nomenclature (ICZN). Nonetheless, taxonomy is dynamic and it is heuristically useful to consider alternatives to the taxonomy proposed by Frost and Etheridge (1989).

(i) *The hybrid approach*.—The recognition of several monophyletic groups within the Iguania is not a recent finding, stemming from the early work of Etheridge and others (Etheridge 1959, 1964, 1966; Etheridge *in* Paull et al. 1976; Etheridge and Williams 1985; Savage 1958) and given cladistic legitimacy by Etheridge and de Queiroz (1988) and Frost and Etheridge (1989). These works promoted common usage of a series of informal names designating the various groups (e.g., anolines, sceloporines, etc.) which came to be widely regarded as subfamilies within the family "Iguanidae." When Frost and Etheridge (1989) elevated these (or very similar) groups to family status, most of these informal names were eliminated, as directed by rules of priority, and the ICZN. Frost and Etheridge (1989), themselves, acknowledged that this aspect of their work would be most controversial. The new names (Polychrotidae, Phrynosomatidae, etc.) disrupted decades of common usage based on reference to Etheridge's original, informal, "subfamily" epithets and might, therefore, be argued to be "destabilizing." As one of the foremost objectives of the ICZN is to promote stability, it is conceivable that an appeal could be made to recognize as formal family names the previously informal subfamilial epithets by addition of the Linnean family ending, -idae. As such, Polychrotidae would become Anolidae (preserving the sense of "anoline") and Phrynosomatidae would become Sceloporidae (sceloporine), etc. This is a hybrid approach in the sense that it accepts the cladistic conclusions of Frost and Etheridge (1989) and use of the ICZN, but at the same time seeks to retain the association between existing names and the clade with which they have previously been identified (de Queiroz and Gauthier 1992; see below). There is a formal appeal process for such exceptions to ICZN rules and stability is one of the principal criteria on which exceptions are allowed. In any case, one would still end up with multiple families where previously there were three, a result unlikely to please many, including Lazell.

(ii) *The metataxon approach*.—Relationships among the recognized groups within Iguania remain obscure owing to contradictory or equivocal evidence (Etheridge and de Queiroz 1988; Frost and Etheridge 1989; Williams 1988). In their study of squamate relationships, Estes et al. (1988) accepted the monophyletic taxa identified by Etheridge and de Queiroz (1988) and could not, themselves, find convincing evidence of "iguanid" and "agamid" monophyly. They represented this ambiguity by designating these families *metataxa*, denoted by an asterisk next to the family name (e.g., Iguanidae* and Agamidae*). This convention was adopted by Gauthier et al. (1988) and these workers for higher taxa and the concept was then extended to species (*metaspecies*) by Donoghue (1985) (note that Donoghue's paper was published first owing to delay in publication of the Gauthier et al. and Etheridge and de Queiroz manuscripts). Kluge (1989) disputed use of the metataxon convention for taxa in which evidence for monophyly is *contradictory*, as opposed to *absent*. In other words, any evidence of paraphyly would eliminate the possibility of monophyly, even if the characters indicating paraphyly are contradictory (incongruent). Kluge (1989) suggested that, in any case, cladistic conventions already exist for such situations (when polytomies result from character incongruence), namely conventions 4 and 6 of Wiley (1981), which place such taxa within a classification as *sedis mutabilis*, or written with shutter quotes and marked *incertae sedis* (see Wiley [1981] for details). In making the latter suggestion (convention 6), Wiley (1981) was simplifying Patterson's (1973) earlier method of using parenthetical codes next to taxon names in a classification to denote mono-, para-, and polyphyletic taxa, and taxa of unknown status. In so doing, Wiley (1981) lumped together known para- and polyphyletic taxa, on the one hand, with taxa of unknown status. Thus, the metaxon situation (for taxa of unknown status; Patterson's [1973] code, [IK]) is actually obscured by the shutter quote/*incertae sedis* convention. According to de Queiroz (*in litt.*), the *sedis mutabilis* convention reflects unresolved relationships among several taxa (i.e., polytomies) and the *incertae sedis* convention reflects the uncertain position of a taxon within a higher taxon, but neither reflects the uncertain monophyletic status of an individual taxon, i.e. the *metataxon* convention.

Kluge (1989:293) further argued that the metataxon convention (as applied to higher taxa) was overly conservative (contra Frost and Etheridge 1993) and potentially constraining, and that it "merely describes a fact about our ignorance." However, this is exactly the intention of the metataxon concept: to call attention to our ignorance about the status of a taxon.

The metataxon convention and Kluge's (1989) paper are important to consider because the latter is central to Frost and Etheridge's taxonomic decision-making. Following Kluge (1989), they rejected the metataxon status of Iguanidae* because there is character incongruence (contradictory evidence of paraphyly). They rejected metataxon status of Agamidae* because it "is not consistent with recovered historical relationships" (Frost and Etheridge 1989:29). It is for these reasons that they chose to recognize as families, *sedis mutabilis*, the largest taxa for which they had reasonable evidence (a strict consensus tree) of monophyly. Once this decision was made, Frost and Etheridge (1989)

used the traditional rules of zoological nomenclature (e.g., the principles of synonomy and priority) and the Linnean system of categorical ranks, resulting in a highly non-traditional classification.

As I indicated above, taxonomic conventions are not writ in stone. For example, one might question Kluge's (1989) restriction of metataxa to groups for which there is merely the *absence* of synapomorphy. Given contradictory evidence of paraphyly (the situation with "Iguanidae"), monophyly of the taxon might be just as likely as paraphyly, despite the present lack of evidence. Character incongruence is a common phenomenon. Do we dismiss the *possibility* of monophyly in the face of it? I have shown that Wiley's (1981) conventions do not precisely distinguish this situation. The metataxon convention, using preexisting names (the approach of Gauthier et al. [1988] and Estes et al. [1988]) might more accurately reflect our current understanding of iguanian relationships while simultaneously promoting taxonomic stability. The asterisk tells us, "don't mistake this for a monophyletic group; relationships within this taxon need to be investigated further," and it does this while preserving names that most workers are familiar with. Such stability of names is usually considered desirable, so long as it does not violate known evolutionary history (which is true at least for Iguanidae*). I am not convinced, as is Kluge (1989), that the metataxon convention will necessarily have a chilling effect, tending to preserve the *status quo*.

(iii) *The phylogenetic taxonomy approach.*—Recent papers by de Queiroz (1992) and de Queiroz and Gauthier (1990, 1992, 1994) propose a radical departure from traditional practices by deriving all taxonomic principles and methods, including those of synonymy and priority, from the central tenet of common evolutionary descent. They show clearly that many aspects of the Linnean system are not compatible with an evolutionary world view and demonstrate that a truly phylogenetic nomenclatural system will have to dispense with many long-held notions. Under their system, taxon names would be very stable because they are defined on the basis of common ancestry and not Linnean categories (de Queiroz and Gauthier 1994). Rules of priority and synonomy would not force abandonment of names traditionally associated with particular lineages, as has occurred with Frost and Etheridge (1989). Both de Queiroz and Gauthier are squamate systematists (Etheridge and de Queiroz 1988; Gauthier et al. 1988; Estes et al. 1988 and other papers) and use the problem of iguanian relationships to illustrate some of their proposals. They note that in a phylogenetic taxonomy, the name Chamaeleonidae would continue to be associated with the undisputed monophyletic taxon with which it has always been associated and that the clade formed by the "agamid" taxa (Agaminae and Leiolepidinae of Frost and Etheridge [1989]) plus chameleons would be named Acrodonta, the name historically associated with that clade. In contrast, in Frost and Etheridge's (1989) taxonomy (based on the traditional use of the Linnean system), Chamaeleonidae is equivalent to "Acrodonta" and therefore includes the traditional agamids, a highly non-traditional usage. Thus, greater taxonomic stability would ensue in the "phylogenetic taxonomic" system, even given Frost and Etheridge's (1989) phylogenetic conclusions. Such stability extends to the fact that lumping and splitting, the latter particularly characteristic of cladistic classifications and deplored by Lazell (1992), would be avoided (de Queiroz and Gauthier 1994).

The proposals of de Queiroz and Gauthier will, undoubtedly, be hugely controversial. One cannot overturn deeply entrenched practices painlessly. However, in my opinion their suggestions need to be considered seriously by all comparative biologists. I urge the readership of *Herpetological Review*, systematists and non-systematists alike, to evaluate "phylogenetic taxonomy" themselves. The pay-off for iguanian systematics specifically and the field of systematics generally is potentially great. Indeed, if accepted, "phylogenetic taxonomy" would obviate most of the discussion herein; questions of paraphyly and metataxa would be things of the past, as would an Iguania comprising nine families (de Queiroz and Gauthier 1994)!

Conclusions

What is clear is that we are in a difficult and undoubtedly protracted transitional stage in systematic biology. We have seen cladistics become preeminent among practicing systematists, despite persistent resistance (e.g., Lazell 1992). Lazell (1992) notwithstanding, the battle is won and biologists must adapt or be peripheralized. However, in the arena of classification and nomenclature, there is much to discuss. The newly proposed system of phylogenetic taxonomy (de Queiroz and Gauthier 1992, 1994) may be the next battlefield.

Although I disagree with most of Lazell's (1992) particulars, I share with him a certain dissatisfaction with the iguanian taxonomy proposed by Frost and Etheridge (1989). I am not persuaded by the arguments against the metataxon convention that would have allowed traditional family names to stand until the weight of evidence showed otherwise. I am not convinced that use of formal family names for traditional "iguanid" taxa, rather than informal names, helps us to understand better evolution within Iguania, so long as we are clear about their monophyletic status. However, these feelings are moot; Frost and Etheridge's (1989) taxonomy will stand or fall depending on usage. Its widespread acceptance in the comparative literature indicates that it is here to stay.

It is possible that a rigorous phylogeny of Iguania will elude us. This terrible possibility stems from the fact that fragmentation and speciation of ancestral iguanians may have occurred over a geologically short period of time and in a geographically contiguous area (Williams 1988). Given virtually simultaneous origin of some or most of the major groups within Iguania, we should expect few clear synapomorphies. The situation is analogous to the origin of the mammalian orders which, to this day, defy unambiguous cladistic resolution (e.g., Novacek 1992). The possibility is that contradictory character distributions and unresolved polytomies reflect the *reality* of the origin of the group (Schwenk and Williams 1989; Williams 1988). Cladistic resolution might be beyond the sensitivity of current morphological and molecular techniques. We must bear this possibility in mind while searching ever deeper for phylogenetic clues.

I have attempted here to clarify some of the issues, as I see them, surrounding current controversy regarding iguanian taxonomy. I conclude that Lazell's (1992) critique of Frost and Etheridge's (1989) methodology is not supportable and suggest that rigorous character analysis is the proper avenue of future investigation. I share with Lazell (1992) some uneasiness about the Frost and Etheridge (1992) taxonomy. I have tried to show, however, that their taxonomy is consistent with current practices, yet is not the only possible outcome. To this end I have explored alternative strategies for dealing with Frost and Etheridge's (1989) phylogenetic results, if only for heuristic purposes, since their classification is a *fait accompli*. Finally, I conclude that a new phylogenetic taxonomy (*sensu* de Queiroz 1992; de Queiroz and Gauthier 1990, 1992, 1994) is sensible and desirable and urge consideration of its proposals.

Acknowledgments.—I thank Bob Hansen, the editor of *Herpetological Review*, for inviting me to comment, and Richard Etheridge, Darrel Frost, Arnold Kluge, and Kevin de Queiroz for their often critical, but always useful, comments and discussion.

TECHNIQUES

Fish Tags For Observing Free-ranging Rattlesnakes

A field study in February 1990 on movements of free-ranging *Crotalus adamanteus* in Jasper County, South Carolina evaluated the use of fish tags for identifying rattlesnakes. Tags needed to be clearly visible at 10 m with binoculars. In addition, each tag needed to contain an address for its return and notification of the researcher in the event the rattlesnake was captured or killed.

Ferner's (1979) review of marking techniques for amphibians and reptiles offered several possible methods, including Pendlebury's (1972) method of attaching colored vinyl discs to the second proximal rattle segment. This would have allowed for identification from a distance, but it would not have provided for the inclusion of a return address.

Floy Tag and Manufacturing (P.O. Box 85357, Seattle, Washington 98105, USA) provided external tags of opaque, flexible plastic (1.5 x 0.5 cm). A hole drilled at each end allowed a monofilament line to be threaded through the holes, looped between the two proximal rattle segments, and knotted as close to the tag as possible (Fig. 1). Excess line was clipped off, and the knots were secured using a single drop of Superglue™. The tags were imprinted with sequential identification numbers on one side and an address and telephone number on the opposing side.

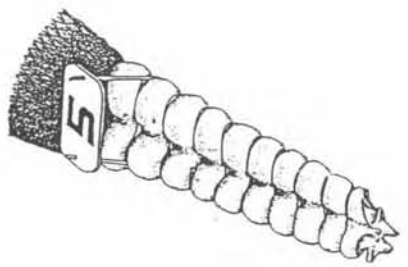

FIG. 1. Installation of fish tag on proximal rattle of *Crotalus adamanteus*.

During the first two months of this study, a total of five small (51–86 cm TL) *Crotalus adamanteus* were tagged. Three snakes were not observed again and one was verified by returned tag as having been killed. One snake, tagged on 7 February 1990, was captured and measured 16 mo later on 10 May 1991. This individual still had the tag attached and had increased its length by 23 cm, demonstrating a potential field use of this identification method with rattlesnakes. An exact life-span of the tags could not be determined, but it may be possible that with occasional replacement of the monofilament line, these tags may remain functional for several years before they are either removed by rattle breakage or disappear with the segmental growth of the rattle by shedding.

HERPETOLOGICAL HUSBANDRY

Captive Management And Breeding Of *Cuora aurocapitata* (Testudines: Emydidae)

The increase in Chinese turtles in the pet trade since 1985, mainly through the efforts of the Hong Kong animal trader Mr. Shiu, has resulted in the availability and the description of several new species. One of these, *Cuora aurocapitata* (Luo and Zong 1988), is a beautifully colored species that is known only from Nanling County, Anhui Province, China, some 300 km west from Shanghai. This species is closely related to *Cuora pani* (Song 1984). The latter occurs more inland in Shaanxi Province and differs in color pattern from *C. aurocapitata*. It has been suggested that *C. aurocapitata* may be a subspecies of *C. pani* (McCord and Iverson 1991). Here, the results of four years of experience with this species in captivity is reported.

A pair of *C. aurocapitata* was obtained via the pet trade in January 1989. Male #1 had a straight-line plastron length (PL) of 10.0 cm and weighed 168 g. Female #1 had a PL of 11.9 cm and weighed 275 g. A second pair of *C. aurocapitata* was obtained in June 1990. Male #2 measured 12.1 cm PL, weighed 275 g, and was missing the portion of the tail posterior to the cloaca. Female #2 measured 14.7 cm PL and weighed 530 g. Microscopic examination of their feces revealed the presence of amoebae; treatment followed with metronidazole (Flagyl, Rhône-Poulenc) 35 mg/kg orally for 10 days.

The first pair was kept in a tank with a water basin measuring 100 X 40 X 20 cm, and an island measuring 40 X 30 cm. Water temperature averaged 22°C. Under a heating lamp mounted above the island the temperature was 27°C. The second pair was kept in a similar tank at first, but because the male was extremely aggressive toward the female he was kept separately in a small tank and introduced to both females approximately 1–2 days every six weeks to encourage mating. Aggressive behavior consisted of biting limbs, head, and shell, and chasing other turtles. Female #2 occasionally exhibited aggression, but could be kept together with other turtles without major difficulties. Male #1 was also placed with female #2 occasionally to facilitate mating, as was male #2 with female #1. They are kept together with other Asian turtles: *Annamemys annamensis*, *Chinemys reevesi*, *Chinemys nigricans*, and *Sacalia bealei "quadriocellata."* They were exposed to 11 h light and 13 h darkness, with the only variation in daylight length being the light coming in through a south-facing window in the room. The animals were fed twice a week on meat mixed with a multivitamin-mineral preparation (Carmix, Hope Farms, The Netherlands), cat food (Brekkies, Effem b.v., The Netherlands), banana, strawberry, and shrimp.

TABLE 1. Growth of hatchling *Cuora aurocapitata*.

	Hatchling #1		Hatchling #2	
Weeks After Hatching	PL	Weight	PL	Weight
2	3.4 cm	10 g	3.1 cm	4 g
8	3.6 cm	12 g	2.9 cm	7 g
18	4.0 cm	15 g	3.5 cm	12 g
28	4.5 cm	20 g	4.1 cm	14 g

Courtship was not restricted to a particular time, but was observed all year. It is less intricate than that reported for *Cuora trifasciata*. Male courtship behavior consisted of approaching the female from the rear, followed by mounting. Once mounted, the male extended his very long neck and the female was bitten and held by her neck. Because of this, the female retracted her head, thereby making her cloaca more accessible. Subsequently, the male would move downwards until his plastron rested on the posterior part of the female's carapace. In this position, penetration was attempted, and sometimes took place. With successful penetration the male would release his neckbite on the female and withdraw his legs from her carapace, after which he was attached to her only by his penis. Mating took place in this position.

On 31 July 1992 one egg was found in the water basin, while female #1 was trying to find a nesting site on land by exploring the island and "smelling" the substrate. She was injected with 60 mg/kg of calcium (Calcium Sandoz) subcutaneously in the rear leg followed by 80 mg/kg two hours later, and subsequently with 6 IU/kg of oxytocin (Piton-S, Organon) intramuscularly one hour thereafter. One hour later one egg was laid, and hour and a half after the administration of oxytocin another egg passed. On 11 August 1992 female #2 was remarkably restless, and palpation of the inguinal regions revealed the presence of eggs. The next day, 80 mg/kg of calcium was given followed by the same dose one hour later, and 6 IU/kg of oxytocin one hour thereafter. One hour later an egg was laid, and 1.5 h later another egg passed. Twelve days later a third egg was laid. The eggs were hard-shelled and oval. Eggs produced by female #1 measured 39 X 21 mm; those from female #2 measured 42 X 24 mm. All eggs were put in moist peat and incubated at 28°C and 95% relative humidity. The 3 eggs produced by female #1 showed no signs of development, eventually became moldy, and were discarded. Of 3 eggs laid by female #2 the first two appeared to be fertile, as a white band developed in the middle of the eggs after 3 days of incubation. After 64 days the two developing eggs showed some cracks at one of the poles. Two days later the hatchlings had opened the eggs with their egg tooth and forelimbs. One hatchling had a large yolk sac which could be seen through the hole. To avoid suffocation in albumen and other egg fluids, the animal was removed from the egg on day 66. It was a very small turtle (31 mm PL, 4 g) with a yolk sac ca. 1 cm in diameter. The animal was placed on a wet tissue and within a few hours the yolk sac had fallen off. The other animal hatched on day 67 and was considerably larger (34 mm PL, 10 g).

One day after hatching, both animals were placed on soaked peat with a little water pan, and 11 days later they were put in an aquarium measuring 20 X 12 cm with 1.5 cm of water. Some weeks later the water level was raised to 5 cm and a flat stone was introduced into the aquarium that provided a platform with a water depth of 2 cm. The smaller animal was more active and ate within a few days of hatching, whereas the other initially refused food during the first days. The animals are presently kept at a temperature of 25°C during the day and 20°C at night. They are fed three times a week on beef heart, cat food ("Brekkies"), or shrimp. Growth of the hatchlings is shown in Table 1.

Our experience indicates that *C. aurocapitata* is relatively easy to manage in captivity. The animals thrive, mate, and females produce fertile eggs when kept in small turtle tanks at moderate temperatures. Nanling County in Anhui Province, the type locality of this species, has a subtropical climate with a mean winter temperature of 5°C and summer temperature of 26°C (Hildebrand 1989; Liangxing 1983). It has yet to be determined whether reproduction can be repeated under these circumstances, or whether these animals need a period of hibernation. The young are voracious feeders, grow quickly, and appear healthy. The smaller of the two neonates has shown a more rapid growth rate. Eighteen weeks after hatching it had increased its body weight by 300%, while the other hatchling had an increase in weight of 150% at that time.

FIG. 1. Hatchling *Cuora aurocapitata*.

RECENT POPULATION CHANGES

Recent Population Changes provides an outlet for anecdotal or minimally documented information on local extinctions or regional population changes. These reports could be valuable historic indications that might enhance our understanding of very long term (>20 yrs) population trends and changes in distribution patterns.

Manuscripts should be submitted directly to the editor of this section: *Ralph W. Axtell, Department of Biological Sciences, Southern Illinois University, Edwardsville, Illinois 62026, USA.*

Factors In The Decline Of *Varanus indicus* On Guam, Mariana Islands

The mangrove monitor (*Varanus indicus*) is a large lizard (to 1.5 m total length on Guam) that has a range encompassing extreme northeastern Australia, New Guinea, and the Solomon, Palau, Caroline, Marshall, and Mariana Islands. Some of these populations may be either pre-historic (Mariana Islands) or historic (Marshall, Palau, and Caroline Islands) human-aided introductions (G. Rodda, pers. comm.; Uchida 1966). The only monitor species in the Mariana Islands is *V. indicus* and the best studied populations occur on Guam where reproductive ecology (Wikramanayake and Dryden 1988), behavior (McCoid and Hensley 1991), observations on reproduction (McCoid 1993a), natural history (McCoid and Hensley 1993), and food habits (Dryden 1965) have been described. A unique attribute of the Mariana Islands is that these are the only U.S.-flagged areas where monitors occur; Guam is a U.S. Territory and the Northern Mariana Islands (all islands north of Guam) is a Commonwealth (CNMI).

While we have no direct estimates of monitor populations in the past, Dryden (1965) inferred that relatively dense populations were present on Guam. Most of the 86 monitors killed in his study (September 1962 to April 1964) were from the Northwest Field area of Guam. Method of collection was to drive along the extensive abandoned runway systems and shoot visible monitors. Although accurate records were not kept, surveys in Northwest Field (1988 through early 1992) by various Guam Division of Aquatic and Wildlife Resource (DAWR) personnel did not reveal as many sightings as was inferred by Dryden's data. Our sightings of *V. indicus* on Northwest Field corroborate the DAWR sightings and indicate that *V. indicus* was far less common than in the early 1960s. Additional data suggesting an overall decline in monitor populations were the number of phone calls (between 1988 and early 1992) to DAWR reporting sightings of monitors by long-time residents of Guam. Most of these calls were prompted because these people had apparently not seen a monitor in a number of years. These two lines of evidence suggest that monitor populations have declined on Guam since the early 1960s. Monitors also appear to be missing from moderately to heavily urbanized areas and exhibit lowered densities in lightly urbanized areas.

A number of factors are probably contributing to the perceived decline in monitor densities on Guam. These include, but may not be limited to, changes in the prey base, effects of urbanization, and the effects of introduced species. In order to place this decline in perspective, two islands with differing pressures and conditions with respect to monitor populations were examined. We compared monitor populations on Guam to Rota, the southernmost island in the CNMI and Guam's closest neighbor. These two islands differ in size (540 km^2 vs. 85 km^2), human population (140,000 vs. 2500), and the number of automobiles (108,000+ vs. <1000).

Prey Base.—McCoid and Witteman (1993) examined changes in the prey base (arthopods, gastropods, and vertebrates) since the 1960's and found major shifts in the dominant prey categories. They found that although substantial changes had occurred, these shifts probably happened in parallel on both Guam and Rota.

Urbanization.—We surveyed on both Guam and Rota by recording localities of DOR individuals. DOR monitors were recorded over a two year period (September 1988 to October 1990) in southern Guam on a 20.2 km section of highway spanning both urban and non-urban regions. This section of highway was driven twice daily between 0700 and 0800 h and 1700 and 1800 h. DOR monitors were recorded on Rota between October 1989 and February 1991, but surveys were conducted at irregular intervals. A regular circuit was not driven and distances traveled were much less than the survey route on Guam. Despite these irregular survey techniques and a shorter sampling period (16 months vs. 25 months) 18 monitors were recorded on Rota, while 28 were recorded on Guam.

To view the effects of human populations on monitor distribution on Guam, we plotted, from our survey route, DOR *V. indicus* with respect to urban areas on Guam. Of the 28 monitors, 19 were associated with non-urban areas. An area was arbitrarily judged urbanized if there was a permanent human dwelling in the immediate vicinity or if substantial habitat alteration, such as a golf course, was present. Approximately half of the survey route was judged non-urban. This pattern was tested with an adjusted $X^2_{(.10[1])}$ test ($X^2_{adj} = 2.89$) and found significant at the 0.10 level. Because of the low human density on Rota, the relationship of monitors to urban areas there was not tested.

Although DOR data from the two islands are not statistically comparable with respect to human occupation, an index of vehicular impact can be generated. Vehicles from several villages along the Guam survey route (Inarajan, Malojloj, Talofofo, and Yona) represented the bulk of traffic. Populations in these villages totaled ca. 6000 people. Proportionately, there would be about 4600 automobiles associated with these villages and an estimated half would be involved in travel daily, yielding an overall kill ratio of 0.012 monitors/auto. On Rota, assuming that only half of the automobiles were involved in daily travel, the DOR ratio is 0.036 monitors/auto. Additionally, automobile traffic travels at much higher speeds on Guam (50 to 70 MPH vs. 30 to 50 MPH on Rota) (pers. obs.). Presumably, higher traffic speeds would cause more DORs. However, since we see proportionately fewer DORs on Guam (about 1/3 of Rota), we view this as evidence for a less dense population of monitors on Guam.

Beside human activities and automobile usage in urban areas, perhaps other effects of urbanization can be discerned on Guam. In the southern Mariana Islands, monitors are viewed as agricultural pests. Many farmers relate stories about predation by monitors on domesticated fowl (Fritts and McCoid 1991; Wiles et al. 1990). Because of this attitude, many people rely on trapping, shooting, and poisoning to eliminate monitors around their property. Additionally, there is a closet enterprise on Guam that supplies monitors to an ethnic group as a traditional food (Auffenberg 1988). Large (>1.2 m), live monitors can be sold to this group for as much as $100.00.

Introduced Species—The southern Mariana Islands have been plagued with a number of recent introductions that have irrevocably reshaped the faunal and floral face of the islands (see Muniappan et al. 1991). Introduced species that are known to have impacted or are suspected of impacting monitor populations are the brown tree snake (*Boiga irregularis*) and (poisonous) toad (*Bufo marinus*). Both Jackson (1962) and Dryden (1965) indicated that monitor populations had decreased on Guam after the introduction of toads. A similar pattern was noted on Palau (Thyssen 1988) and Pohnpei (Jackson 1962). Uchida (1966) mentioned that *B. marinus* had been considered for introduction to control monitor populations in the western Caroline Islands. All these authors noted that *V. indicus* would prey on these conspicuous toads. Populations of *B. marinus* occur in the southern Mariana Islands

(Rodda et al. 1991; McCoid 1993b). This species probably still plays a major role in limiting *V. indicus* as recent surveys indicated *B. marinus* densities as high as 35 adult toads/ha in non-urban areas (G. Rodda, pers. com.). Rodda et al. (1992) recorded snake densities as high as 100 per hectare on Guam, and Savidge (1988) recorded *V. indicus* as a prey item of *B. irregularis*. Larger snakes (> 1.5 m total length) are generally associated with urban areas on Guam (McCoid 1989) and may, because of size, be more likely to prey on monitor lizards, perhaps accounting for some of the lessened densities of monitors observed in urban situations. There is no established population of *B. irregularis* on Rota (McCoid and Stinson 1991).

Other introductions are feral mammals (dogs, cats, and pigs) that have reached substantial densities in the southern Mariana Islands. On Guam, the Department of Public Health and Social Services estimated that feral dogs had, at one time, reached a population of 30,000. Impacts on other vertebrates are poorly understood but there are reports of feral dogs killing domesticated fowl, deer, pigs, and monitors. There is no information on the number of feral dogs on Rota. Population estimates of feral cats for the southern Mariana Islands are not known but were frequently encountered on Guam and Rota. In other areas with feral cats, enormous damage to wildlife has been reported (Mitchell and Beck 1992). Conry (1989) noted that while feral pigs on Guam did consume reptiles, animal protein formed a relatively minor component of their diet. However, since 1980, feral pig populations on Guam have undergone a dramatic increase (Conry 1989). Feral pigs were not known from Rota until 1991 (C. Rice, pers. comm.).

It is likely that a suite of factors have contributed to the decline of monitors on Guam. Islandwide population declines may be attributable to the introduction of *B. marinus*. Other feral and introduced species have likely played lesser roles in widespread and localized declines of monitors on Guam. Local extirpations are probably due to the degree of urbanization.

While it is unlikely that *V. indicus* will be completely extirpated from Guam, it is likely that this species will experience further restriction of range to areas that are currently undeveloped, federally or territorially protected, or have little development potential. It is also likely that *V. indicus* will suffer decreasing population levels in all remaining areas of occurrence in the southern Mariana Islands.

Acknowledgements.—We thank Gordon Rodda (National Biological Survey) for his observations on toads and Cliff Rice (CNMI Dept. Natural Resources) for information on feral pigs on Rota. Robert Haddock kindly supplied data from the Guam Department of Public Health and Social Services. Demographic data were obtained from the offices of the U.S. Representatives to Congress, Rep. Underwood (Guam) and Rep. Babauta (CNMI). Robert Cruz, Mary Taylor (DAWR), and Estanislao Taisacan (CNMIDNR) aided in this study. Portions of this study were supported by the Endangered Species Conservation Program, Project E-4 to Guam.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 25, number 1.

CAUDATA

SIREN LACERTINA (Greater Siren). **DIET**. Although *Siren lacertina* is generally regarded as an opportunistic feeder on a variety of invertebrates, small fish, and plant matter, several authors have reported that mollusks are important in the diet. Hamilton (1950. Nat. Hist. Misc. 62:1–3) reported that "large individuals of *Siren* feed principally upon snails and insects" and that a "large *Siren lacertina* often contains a half pint of snails." Burch and Wood (1955. Copeia 1955:255–256) reported finding 138 mollusks of five species in the stomach of a single adult (369 mm SVL) *S. lacertina* from Virginia; 120 (87%) of these were of the sphaeriid clam *Musculium jayense*. Duellman and Schwartz (1958. Bull. Florida State Mus., Biol. Sci. 3:181–324) examined stomachs of 9 *S. lacertina* from southern Florida and found 18 insects, 2 crayfish, and 1 small fish, but they found no mollusks.

While electroshocking on 16 April 1992, personnel of the Florida Game and Fresh Water Fish Commission collected a moderate-sized (325 mm SVL, 481 cm TL; UF 86818) *S. lacertina* from Orange Lake, Alachua County, Florida. The abdomen of the specimen was obviously distended. Following several days in captivity, the siren passed shells from a total of 324 snails (323 *Planorbella scalare*, 1 *Physella pumila*) and 1 clam (*Musculium* sp.). The *P. scolare* varied in size from 4.5 to 9.1 mm in maximum diameter. In addition to the mollusks, the excreta included a pair of crayfish gastroliths. This report confirms earlier findings that some *Siren lacertina* may prey heavily on mollusks. However, this specimen had taken primarily snails, whereas the Virginia specimen reported by Burch and Wood had preyed predominantly on bivalves.

L. Mantini and R. A. Myers collected the siren and made it available. F. G. Thompson identified the mollusks.

TARICHA TOROSA (California Newt). **DIET**. Adult California newts typically feed on earthworms, insects, snails, and other small invertebrates (Stebbins 1972. California Amphibians and Reptiles. Univ. of California Press, Berkeley, 152 pp.). Other studies have found that adult newts cannibalize egg masses and larvae (Kaplan and Sherman 1980. J. Herpetol. 14:183–185.; Kats et al. 1992. Herpetol. Rev. 23:7–8; Elliott, Kats, and Breeding, unpubl. data).

On 4 June 1993 we used water lavage to flush the stomach of a female newt (6.5 cm SVL, 9.8 g) captured in a small, first order stream in the Santa Monica Mountains (Los Angeles Co., California). The contents of the stomach of this relatively small adult included several insects: 2 coleopterans, 1 lepidopteran, and 1 plecopteran. In addition, we found 5 conspecific newt larvae (10–15 mm TL) in the stomach contents. The most conspicuous animal found in the newt's stomach was a nestling bird. The small bird (0.30 g) was fully intact, including clearly visible wings, legs, and head. We often see Anna's hummingbirds nesting over stream pools. We assume that the newt preyed on the small bird after it fell from a nest above the stream pool. We believe this is the first record of a bird being found in the diet of a newt.

ANURA

BUFO PARACNEMIS (Sapo Rococo, Kururú Guazú, Sapo Buey). **MALE REPRODUCTIVE BEHAVIOR**. Wells (1977. Anim. Behav. 25:666–693) classified temporal patterns of anuran reproduction into two broad categories: prolonged breeding and explosive breeding. I observed a chorus of *Bufo paracnemis* in order to examine fidelity of males to chorus sites and patterns of spacing among individuals. A total of 50 male *B. paracnemis* were marked in a temporary pond during eight occasions between October and December 1988 at Finca San Javier, 8 km S Joaquin V. Gonzalez, Salta, Argentina. The size distribution of the males was unimodal, with a mean SVL of 180.2 mm (N = 50; SD = 30.84, range = 150–240). Observations of male-male encounters and positions of calling sites were made during the activity period which usually lasted from 1900–0100 h. The number of individuals in the chorus varied on a nightly basis from 2 to 15 (N = 8; mean = 8.25; SD = 4.2). Some individuals failed to appear while others appeared for the first time. There was no correlation between body size and the number of nights toads were present at the pond (N = 50; r = 0.016; P > 0.25). The number of times an individual appeared at the pond during the study varied between one and eight (N = 50; mean = 2.3; SD = 1.6). Calling sites of individual males changed among nights, but an individual always stayed at the same site during one night even after natural agonistic interactions with an intruder.

Wells (*op. cit.*) postulated that male-male aggression without site attachment should lead to maintenance of inter-individual distances in a breeding chorus. I observed 11 naturally occurring agonistic interactions between males. The distance between combating males was < 0.5 m on all occasions. A simple experiment was performed in the field. On four opportunities, males of similar size were placed on the site of a neighboring male to simulate invasion by an intruder. In all four cases the resident male forcefully expelled the intruder. The intruder then returned to his initial site. In conclusion, *B. paracnemis* at my study site exhibited the characteristics of a prolonged breeder: breeding choruses occurred for more than a month; males called from stationary positions on a given night; and minimum inter-male spacing was maintained at the breeding pond.

I thank L. A. Fitzgerald for encouraging me to carry out this work. M. L. Crump, F. B. Cruz, L. A. Fitzgerald, E. O. Lavilla, R. L. Laurent, and G. Scrocchi gave helpful comments.

CROCODYLIA

CAIMAN LATIROSTRIS (Broad Snouted Caiman). **OMPHALOPAGUS TWINS**. Within the Crocodylia, monozygotic twins have been observed in *Crocodylus porosus* (Webb 1987. *In* Webb et al. (eds.), Wildlife Management: Crocodiles and Alligators, pp 417–422. Surrey Beatty and Sons, Sydney), *Crocodylus acutus* (Neill 1971. Alligators, Crocodiles and their Kin. Columbia University Press, New York. 486 pp), and *Alligator mississippiensis* (Reese 1906. Anat. Anzeigen Jena 28:229–231). We report three occurrences of omphalopagus twins (fused at the umbilicus) (Lewis et al. 1992. Herpetol. Rev. 23:69–70) of *Caiman latirostris*, and describe some macroscopic features of these fusions.

Case 1: A nest of 40 eggs was laid on 27 December 1991 at the Experimental Breeding Station, Ministerio de Agricultura y Ganaderia Argentina, Santa Fe, Santa Fe Province, Argentina. The egg containing twins was larger than typical (82 x 42 mm). After 78 days of incubation at 30°C and 95% humidity, 31 eggs hatched or were manually opened. The egg containing twins was manually opened. Both twins were well formed but one was dead.

Inside the egg, the twins were oriented in opposite directions. The live twin measured 18 cm TL and weighed 29 g, and the dead one was 17 cm TL and weighed 24 g. At age 10 mos the survivor was 30.5 cm TL and weighed 124 g, much smaller than average caimans of this age reared in captivity (mean TL = 43 cm, SD = 5.6 cm; mean mass = 325 g, SD = 151 g) (Larriera 1993. *In* Zoocria de los Crocodylia. Memorias de la I Reunion Regional del CSG de la IUCN. The World Conservation Union, Gland, Switzerland. ISBN 2-8317-01-47-3).

Case 2: A nest of 42 eggs was collected from the wild as part of the Monitoring and Restocking Program, Estancia el Lucero, San Cristobal District, Santa Fe Province, Argentina (29°55'S, 60°50'W) on 18 February 1992. After 20 days, 40 eggs hatched. One normal sized egg contained twins. One of the twins was well formed, alive, and measured 17 cm TL and weighed 33 g. A small malformed live embryo was attached, but not viable. It was surgically separated and died. Two days later the other twin died.

Case 3: A nest of 44 eggs was collected from the wild on 19 February 1992, and after 40 days, 36 eggs hatched. One normal sized egg contained twins. They were alive and completely formed, but small, measuring 15 cm TL each and weighing 18 and 20 g, respectively. They were surgically separated, but both died one day later.

In all three cases, twins shared the yolk and only one of the animals was still alive as of November 1993. The three cases of omphalopagus twins accounted for 0.26% of the total number of eggs (1166) collected during the 1991-92 season.

TESTUDINES

CARETTA CARETTA (Loggerhead Sea Turtle). **NESTING.** Nesting loggerhead sea turtles (*Caretta caretta*) with maimed or missing hindlimbs typically may make several attempts to dig egg chambers before aborting. When eggs are deposited, many are broken or exposed during nest closure. Occasionally, eggs are simply laid on a flat beach (Dodd 1988. Synopsis of the Biological Data on the Loggerhead Sea Turtle *Caretta caretta* (Linnaeus 1758). U.S. Fish Wild. Serv. Biol. Rept. 88(4). 110 pp.). Field workers have successfully excavated egg chambers for loggerheads with these deformities (LeBuff, pers. comm.). This note documents reproductive dysfunction of a loggerhead with anatomically intact but movement impaired hindlimbs.

A female turtle (tagged QQN 226, straight carapace length = 82.2 cm, width = 65.2 cm) with a deep t-shaped fracture on the left posterior portion of her carapace was observed on Key Island south of Naples, Florida. The short arm of the injury (10 cm) crossed her backbone diagonally while the longer portion (25 cm) paralleled her backbone on the left rear of her carapace. Vertebral scute 4 was fractured and pushed inward. The injury appeared boat related and impaired normal hindlimb movement.

QQN 226 was first seen on 19 May 1991 when she dug two shallow, ill-formed egg chambers before aborting. Between 20 and 23 May she made five false crawls. She nested on 26 May. Between 6 and 8 June, QQN 226 made four false crawls before nesting on 10 June. She nested once more on 26 June.

Loggerhead nesting behavior has been partitioned into 18 steps (Hailman and Elowson 1992. Herpetologica 48(1):1–29). Of these, QQN 226 completed only sand flicking and right and left posterior shift outward movements. She was able to dig and scoop sand with her right limb only to a depth of ca. 20 cm. She could dig with her left limb but could not curl it to scoop sand from the cavity. The repeated false crawls were probably the result of her inability to dig an egg chamber.

Staff augmented her nesting each time by removing sand from the depression whenever she shifted her carapace outward. In each case, laying eggs before the egg chambers were the normal depth, ca. 43 cm (LeBuff 1990. The Loggerhead Sea Turtle in the Eastern Gulf of Mexico. Caretta Research, Inc. Sanibel, Florida. 216 pp.). All the nests were too shallow and were relocated. While QQN 226's clutches were smaller than most loggerhead clutches (mean QQN 226 = 83, N = 3; mean all = 96, N = 168), hatching success was high (mean QQN 226 = 97.6%). Her ability to produce viable eggs was apparently not affected by the injury. This observation documents an indirect consequence, reproductive dysfunction, of human-caused injury which may be less conspicuous than direct mortality or reduced viability, but which has the same result.

My thanks to Michelle Conant, Stephanie Richardson, Doug Chaltry, and Tracy Darnell for their efforts during the 1991 nesting season.

Submitted by **DAVID S. ADDISON**, Environmental Protection Division, The Conservancy, Inc., 1450 Merrihue Drive, Naples, Florida 33942, USA.

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **BILLFISH INTERACTION.** The occurrence of billfish such as marlin (*Makaira* spp.) and sailfish (*Istiophorus* spp.) bills broken off in loggerhead (*Caretta caretta*), green (*Chelonia mydas*), olive ridley (*Lepidochelys olivacea*), and leatherback (*Dermochelys coriacea*) sea turtles has recently been summarized by Frazier et al. (1994. Env. Biol. Fishes 39:85–96).

Here, we report one case of a marlin bill found in a leatherback sea turtle. On 5 May 1993, a female leatherback sea turtle (CCL = 153.0 cm) nesting on Sandy Point National Wildlife Refuge, St. Croix, U.S. Virgin Islands, was found to have the distal portion of the bill of a blue marlin (*Makaira nigricans*) protruding vertically from its carapace, 19 cm posterior to the left anterior tip. The broken end of the bill was exposed 1.5 cm and heavily fouled with algae (species unknown) and large gooseneck barnacles (*Lepas* sp.). The bill was easily extracted with a slight pull. A fibrous membrane had formed around the bill where it was encased in the body. The resulting hole in the carapace had healed around its circumference and there was no bleeding upon extraction. Width of the hole at the skin surface was 2 x 3 cm with a depth of 6 cm. The hole was directly over the left lung of the turtle, and a pink membrane could be seen at the bottom of the hole, expanding 1 cm into it as the turtle breathed. We do not know whether the bill had penetrated the dorsal surface of the lung and subsequently healed. Approximately 3.5 cm of the distal tip of the bill was worn away; it is impossible to know if this happened before or after its insertion in the turtle. Dimensions of the bill (3.0 x 5.0 x 1.75 cm) suggest that it was probably from a female blue marlin > 295 kg (Harry Fierstine, pers. comm.).

After removal of the bill the turtle returned to lay its fifth nest of the season on 15 May 1993. The wound was smaller at this time and appeared to be filling in.

Funding for the leatherback sea turtle research at Sandy Point National Wildlife Refuge comes from Earthwatch Expeditions, Inc., Hubbs-Sea World Research Institute, and the U.S. Fish and Wildlife Service (Endangered Species Cooperative Agreement with the U.S. Virgin Islands Division of Fish and Wildlife). The authors would like to thank Harry L. Fierstine of California Polytechnic State University for identification of the marlin bill, Jack Frazier of CINVESTAV for a copy of the manuscript on billfish attacks on sea turtles, and the Caribbean National Wildlife Refuge office for permission to conduct our studies at Sandy Point NWR.

Submitted by **SCOTT ECKERT** and **DONNA McDONALD**, Hubbs-Sea World Research Institute, 1700 South Shores Road, San

Diego, California 92109, USA, and **PETER DUTTON**, Department of Biology, Texas A&M University, College Station, Texas 77843, USA.

GOPHERUS POLYPHEMUS (Gopher Tortoise). **MAXIMUM SIZE**. The maximum size for *Gopherus polyphemus* is 38.1 cm (carapace straight-line measurement) (Conant and Collins. 1991. A Field Guide to Reptiles and Amphibians of Eastern North America, 3rd ed., Houghton Mifflin Co., Boston, Massachusetts. 450 pp.) from a tortoise captured near LaBelle, Hendry County, Florida in 1974 (P. C. H. Pritchard, pers. comm.). On 13 February 1992, William Stokes encountered a large tortoise (carapace straight-line measurement = 38.7 cm; weight = 10.7 kg) in sand pine scrub at Jonathan Dickinson State Park in Martin County, Florida. The short gular projection and shallow plastral concavity of this new record tortoise suggest it is a female, but since it is a giant we will not guarantee the gender. The turtle was photographed, marked, and released in the area of its capture. Literature on large *G. polyphemus* includes the following. Theodore Roosevelt (1917. Notes on Florida Turtles. Amer. Mus. Jour. 17:289–291) stated that gopher tortoises reached a shell length of 18 inches (over 45 cm) but this claim was discounted (Carr. 1952. Handbook of Turtles. Cornell Univ. Press, Ithaca, New York. 542 pp.). Ernst and Barbour (1972. Turtles of the United States. Univ. Press Kentucky, Lexington. 347 pp.), were reportedly shown photographs of a 40.6 cm, 13 kg male tortoise that came from the Brighton Indian Reservation (Glades Co., Florida). The specimen has never been available for examination. *Gopherus polyphemus* probably reaches a maximum length of about 40 cm. Caution must be taken when measuring large turtles because inaccurate (and longer) carapace measurements can be obtained by moving the calipers at angles to the mid-line of the carapace. We recommend measuring large, living specimens with calipers at least ten times and giving the result as an average of those measurements.

We gratefully acknowledge the contributions, advice, and encouragement of Peter C. H. Pritchard of the Florida Audubon Society.

MACROCLEMYS TEMMINCKII (Alligator Snapping Turtle). **REPRODUCTION**. Evidence of natural reproduction by this species in the northern half of its range is lacking. Minton and Minton (1973, Giant Reptiles, Charles Scribner's Sons, New York, 345 pp.), suggested that the northernmost breeding population is in southern Illinois. This was based on the record supplied by E. C. Galbreath and published by Smith (1961, The Amphibians and Reptiles of Illinois, Illinois. Nat. Hist. Surv. Bull. 28:1–298) of "a female ready for oviposition" taken in Union County. Caldwell and Collins (1981, Turtles in Kansas, AMS Publ., Lawrence, 67 pp.) noted that *M. temminckii* mated in the Arkansas River in Kansas. On 22 June 1992, a small (maximum carapace length (CL) 51 mm, midline CL 46 mm, weight 35 g) *M. temminckii* was captured in a hoop trap by Laura Walker and John Koons from the east side of Kentucky Lake (impounded Tennessee River) at river km 89.3 (mi 55.5) in the bay fed by Tischel Creek, 10.3 river km (6.4 mi) S of the Tennessee/Kentucky border in Stewart County, Tennessee. The specimen was photographed (APSU 4738, color slide), weighed, measured, marked, and released at the capture site. This find represents the first documented case of successful natural reproduction by *M. temminckii* in any part of its range north of central Louisiana (Dobie 1971. Copeia 1971:645–658).

Thanks to David Snyder, Jim Dobie, and Charles Rozelle for reviewing the manuscript. This work was supported by funding provided by The Center for Field Biology, Austin Peay State University.

Submitted by **A. FLOYD SCOTT**, Department of Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA, and **JOHN KOONS**, Department of Natural and Physical Sciences, Jackson State Community College, Jackson, Tennessee 38301, USA.

TERRAPENE CAROLINA CAROLINA (Eastern Box Turtle). **REPRODUCTION**. Female *Terrapene carolina* containing oviductal eggs have been recorded in Virginia from 26 May to 25 July (Mitchell, *in press*. The Reptiles of Virginia. Smithsonian Inst. Press, Washington, D.C.). Other reports of reproduction in *Terrapene* (see list in Ernst and McBreen 1991. Cat. Amer. Amphib. Rept. 512.1–512.13) indicate that nesting occurs in late spring and early summer throughout its range.

On 9 October 1992, we found a road-killed, 121.5 mm plastron length, gravid female in Newport News City Park, Newport News, Virginia. Presumably she had been active following rains during the morning and previous night and was killed between 1330 and 1430 h EDT. A hatchling *Chelydra serpentina* covered in mud was also found on the road at that time. The female *T. carolina* contained three oviductal eggs, two of which were broken when she was crushed. The third measured 35.5 x 19.2 mm and weighed 7.9 g. Two vitellogenic follicles measuring 14.1 mm and 11.6 mm occurred on the right side and three smaller follicles, 5.2 mm diam, were present on the left side. The unbroken egg was incubated in the laboratory but development did not occur.

We are unaware of other reports of oviductal eggs in *Terrapene carolina* in the fall season. Three competing hypotheses account for this observation. (1) The female was a resident of the park seeking a nest site for oviposition. Consequently, if the eggs had survived, they would have overwintered in the nest. If true, then it is unlikely that embryonic development could have taken place after mid-October at this latitude. Thus, the eggs of this species may sometimes undergo embryonic diapause (Ewert 1985. *In* C. Gans et al. (eds), Biology of the Reptilia, Development A, Vol. 14, pp. 72–267, John Wiley & Sons, New York). (2) The eggs could have been retained in the resident female's oviducts without embryonic development and overwintered along with her. The eggs could then have been deposited the following spring. Egg retention in natural populations has been documented for periods of several weeks in emydids and kinosternids (Moll 1979. *In* Harless and Morlock (eds.), Turtles: Perspectives and Research, pp. 305–331, John Wiley & Sons, New York) but there are no reports of turtles retaining eggs over winter under natural conditions. (3) The female was a recently released captive that had retained her eggs throughout the summer and early fall. Turtles kept in captivity routinely retain eggs in the oviducts when nesting conditions are lacking and are occasionally discovered with eggs in the body cavity as long as several months after capture (Cagle and Tihen 1948. Copeia 1948:66). We were unable to determine whether any of the crushed eggs were in the female's body cavity. Thus, we cannot say for certain that the female was not a former captive that had been recently released in the park. The lack of abnormal wear patterns on the plastron and claws provides circumstantial evidence that she was at least not a long-term captive. Additional observations of naturally occurring ovigerous *T. carolina* in the fall season and of egg retention in captives would help to establish which of these hypotheses is valid.

LACERTILIA

ANOLIS CAROLINENSIS (Green Anole). **INTERSPECIFIC BEHAVIOR**. Reptile interactions with birds generally involve predation of one group upon the other, but competitive interactions apparently have been rarely observed. The green anole is characterized as a diurnal, insectivorous lizard. Between 10 September and 29 October 1992, near a house in Edinburg, Hidalgo County, Texas, I frequently observed at least three (based on size and sex) *A. carolinensis* feeding in flower bracts of a group of ornamental plants with conspicuous red, trumpet-shaped flowers (identity unknown but locally called firecracker bush). No other plants were blooming during October. Feeding behavior consisted of deliberate licking of the stamens or the interiors of the flowers suggesting that lizards were feeding on pollen and nectar, and not insects associated with the flower bracts. Between 21 October and 29 October 1992, at least one female black-chinned hummingbird (*Archilochus alexandri*) also fed on these flower bracts. *Archilochus alexandri* is a migrant in south Texas during September and October (Peterson 1985. Birds of Texas and Adjacent States, Easton Press, Norwalk. 304 pp.). When the hummingbird was present, she repeatedly attacked and forced the *A. carolinensis* from flower bracts. About twenty attacks were noted. After displacing an *Anolis* from a flower bract, the hummingbird fed at that and other unoccupied bracts. Attacks consisted of repeated close, rapid, darting approaches with the tail feathers fanned. Other *A. carolinensis* conspicuously perched in the same plants, but not on flower bracts, were also attacked and forced to descend. At one time, an oddly folded leaf (which I mistook for a perched *Anolis*) was repeatedly attacked by this hummingbird. Unidentified large dipterans, honey bees, and bumble bees feeding on nectar or pollen were also attacked by the hummingbird. Earlier in the year, no interactions between *Anolis* and other species of hummingbirds were observed. Conversely, I did not observe nectar feeding in *Anolis* before September 1992.

These behaviors suggest that floral resources may be limiting at certain times of the year and contribute to the aggressive interactions between hummingbirds, anoles, and insects.

Helpful comments were supplied by Rebecca A. Hensley and logistic support supplied by Rosemary Hensley.

Submitted by **MICHAEL JAMES McCOID**, Caesar Kleberg Wildlife Research Institute, Texas A & M – Kingsville, Kingsville, Texas 78363, USA.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). **OOPHAGY**. Intraspecific oophagy by lizards, in general, is well documented. However, there are few reports for the genus *Cnemidophorus*. In *C. uniparens* three cases of oophagy in captivity by conspecifics have been reported (Crews et al. 1983. *In* Huey et al. (eds.), Lizard Ecology: Studies of a Model Organism, pp. 205–231. Harvard Univ. Press, Cambridge, Massachusetts.). Oophagy has been reported in captive, reproducing colonies of parthenogenetic whiptail lizards, but the species in question is unclear (Townsend 1979. Int. Zoo Yrbk. 19:80–86). In none of these cases did a lizard eat her own eggs.

In May 1992 we collected *C. sexlineatus* from northern Arkansas and brought them back to our laboratory in Wisconsin. The lizards were watered and fed crickets daily. Every third day crickets were dusted with Theralin Puppy Nutritional Powder. Lizards were housed in plastic rat cages containing sand and shelter with heat lamps and full spectrum fluorescent lights.

One cage contained a male and a gravid female. On 3 June 1992, the eighth day of acclimation, the male was eating a desiccated egg. The female bit off a piece protruding from the male's mouth. There were bits of yolk scattered on the sand. After a few minutes the empty shell was dropped. Although brought to their attention, a second desiccated egg was not eaten by either lizard during a 24-hour period. We placed a fresh *C. sexlineatus* egg, 0.94 g, which had been incubating for 4 days at 28°C in the cage. Within seconds the male approached, flicking his tongue, picked up the egg and ruptured it with the first bite. After about 28 min the male had consumed the contents of the egg and the shell.

Mitchell and Groves (pers. comm.) suggest several hypotheses to account for intraspecific oophagy. We did not explicitly test any of these. However, calcium deficiency seems unlikely, as the nutritional powder used to dust the crickets contains a minimum of 11.3% calcium by weight.

We thank Joseph C. Mitchell for his help with this paper, and Stanley E. Trauth for his assistance with the field work.

DRACO VOLANS (Flying Dragon). **REPRODUCTION**. At 1100 h on 16 February 1993 at the Dallas Zoo (photoperiod = 10L:14D, temp. 32°C) an adult female *D. volans* (SVL 80 mm, TL 149 mm) constructed a nest by forcing her head into potting soil and repeatedly rotating her body in a clock-wise direction. This action produced a depression ca. 3 cm deep. Five eggs (mean size 11.6 X 7.7 mm, 0.4 g) were deposited in the depression. The female covered them by pushing soil over the eggs with her head. Vertical head bobbing motions were used to pack the soil solidly (as described by Magdefrau 1992. The Vivarium 4(1):14).

The female guarded the nest from staff members during the hour following oviposition. This aggression consisted of lunging, biting, and expansions of the patagium. Although the eggs were removed one hour after oviposition, the female remained on or near the nest site for ca. 24 h. No further nest guarding behavior was exhibited.

Five neonates hatched (mean SVL = 9 mm, TL = 21 mm, 0.3 g) after an incubation period of 32 days. Nothing is known regarding reproductive behavior of this species in the wild.

Submitted by **WINSTON C. CARD**, Department of Herpetology, Dallas Zoo, 621 East Clarendon Drive, Dallas, Texas 75203, USA.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **ARBOREAL BEHAVIOR**. *Phrynosoma cornutum* is a ground-dwelling lizard that often burrows into the rocky, sandy, or loamy soils in which it is found (Smith 1946. Handbook of Lizards. Comstock Publ., Ithaca, New York, pp. 290-293.). This species has a broad geographic range and occupies a variety of open desert and grassland habitats, preferring sparsely vegetated areas (Price 1990. Cat. Amer. Amphib. Rep. 469:1–7). This note documents the climbing of, and roosting in, trees by *P. cornutum*, a behavior not previously reported in this species.

On 17 June 1992 at ca. 2300 h, two adult *P. cornutum* were discovered ca. 0.75–1.0 m up on the trunk of a blackjack oak (*Quercus marilandica*) about 6.4 km south of Harrah, Oklahoma County, Oklahoma. The habitat consisted of a stand of sparsely spaced blackjack oaks with surrounding grassland. There were no rocks in the immediate area and the soil was sandy. However, the ground was very wet from heavy rainfall earlier in the day. The lizards chose an oak about 2 m from an open, grassy area. Both individuals were sitting on the tree facing up with their eyes closed as if they were sleeping. By 0900 h the next day, both lizards were gone. In addition to this record, a local herpetologist reported *P. cornutum* climbing 1-2 m up sycamore trees (*Platanus occidentalis*) in riparian habitats in Noble County, Oklahoma after heavy rainfall.

HERPETOLOGICAL NATURAL HISTORY

Herpetological Natural History **is a peer-reviewed journal devoted to all aspects of natural history (e.g., behavior, biodiversity surveys, conservation biology, disease, ecology, evolution, geographic distribution, paleontology, reproduction) of free-ranging amphibians and reptiles. U.S. subscriptions to *Herpetological Natural History* are $25.00/yr. International subscriptions are mailed by surface and require an additional $5.00 for postage. Air mail quotes will be provided upon request. Back issues (1993) are available at $17.00/number (postpaid). Payment (by check or money order and in U.S. Dollars) should be made to: International Herpetological Symposium, Inc.**

Horned lizards occasionally climb into low shrubs (ca. 0.5 m or less in height) during the hottest part of the day to escape the hot ground temperatures (Whitford and Bryant 1979. Ecology 60:686–694). However, they are not morphologically adapted for climbing. They possess relatively short legs and are slow and awkward (Pianka and Parker 1975. Copeia 1975:141–162). They do, however, possess relatively long, sharp nails on each toe that might facilitate climbing. Although sometimes found in moist soils, *P. cornutum* does not favor wet soil conditions. We believe that the climbing behavior documented here is a tactic in response to flooding or other saturation of their soil habitat.

Submitted by **STEVEN R. SHEFFIELD**, Department of Zoology, Oklahoma State University, Stillwater, Oklahoma 74078, USA, and **NEIL CARTER**, Department of Herpetology, Oklahoma City Zoo, Oklahoma City, Oklahoma 73111, USA.

PHRYNOSOMA MCALLII (Flat-tailed Horned Lizard). **PREDATION**. There are few published accounts of predators of *P. mcallii* (Funk 1965. Herpetologica 21:15–17; 1981. Cat. Amer. Amphib. Rept. 281:1–2; Ross 1989. Amphibians and Reptiles in the Diets of North American Raptors. Wisconsin Endangered Species Research Report 59, Wisconsin Dept. of Natural Resources, Madison, 33 pp.). We identified some avian and mammalian predators of *P. mcallii* by analyzing remains of carcasses in the field. This work was conducted March–July 1979, as part of an intensive survey to delineate the distribution of *P. mcallii* in California (Turner and Medica 1982. Copeia 1982:815–823). Additional data were collected from May–June 1980 in the Coachella Valley near Palm Springs, Riverside County, California. Remains of *P. mcallii* were identified using diagnostic characters for this species (Smith 1946. Handbook of Lizards, Comstock Press, New York, 557 pp.; Stebbins 1954. Amphibians and Reptiles of Western North America, McGraw-Hill Book Co., New York, 528 pp.).

Habitat where the *P. mcallii* remains were found was characteristic of Sonoran Desertscrub, Lower Colorado River Valley Subdivision, Creosotebush (*Larrea tridentata*)-White Bursage (*Ambrosia dumosa*) Association (Brown and Turner 1982. Sonoran Desertscrub, *In* D. E. Brown (ed.). Biotic Communities of the American Southwest—United States and Mexico, pp. 181–221. Desert Plants 4:1–342). Three remains were found in association with bird nests: 1) an American kestrel (*Falco sparverius*) nest in an abandoned building in the Yuha Basin west of Mount Signal, 15 km SW El Centro, Imperial County, California; 2) a common raven (*Corvus corax*) nest in the Superstition Mountains, on the National Parachute Test Range and Naval Air Facility, 28 km W Brawley, Imperial County California; and 3) a burrowing owl (*Athene cunicularia*) nest, 20 km SW El Centro, Imperial County, California. We also identified two partially eaten *P. mcallii* that were presumably the prey of loggerhead shrikes (*Lanius ludovicianus*); one was found impaled on a barb-wire fence at Brock Agricultural Research Center, 6 km E Midway Well, Imperial County, California, and another was found on the spine of a western honey mesquite (*Prosopis glandulosa* var. *torreyana*) near Bob Hope Drive, Palm Springs, Riverside County, California.

Avian predators of other *Phrynosoma* species include red-tailed hawk (*Buteo jamaicensis*), prairie falcon (*Falco mexicanus*), greater roadrunner (*Geococcyx californianus*), common raven (*Corvus corax*), thrashers (*Toxostoma* spp.), and other raptor species (Bryant 1911. Univ. California Publ. Zool. 9:1–84; Knowlton and Stanford 1942. Copeia 1942:186; Miller 1948. Copeia 1948:67; Munger 1986. Copeia 1986:820–824; Sherbrooke and Montanucci 1988. J. Arid Environ. 14:275–284; Ross 1989, *op. cit.*; Sherbrooke 1990. Wilson Bull. 102:171–174; W. C. Sherbrooke, pers. comm. 17 March 1992). Published accounts of reptilian flat-tailed horned lizard predators include the sidewinder (*Crotalus cerastes*; Funk 1965, *op. cit.*).

Kit fox (*Vulpes macrotis*) was the only mammalian predator of *P. mcallii* we identified. We located the remains of an uneaten, but chewed individual on the mound of an active kit fox den, ca. 10 km E of the Fish Creek Mountains, Imperial County, California. Kit fox are known lizard predators (Jameson and Peters 1988. California Mammals. Univ. California Press., Berkeley, 403 pp.), but to our knowledge there are no published reports of their predation on *P. mcallii*. Squirting blood from sinuses surrounding the eyes by *Phrynosoma* species has been described as an anti-canid defensive behavior, but blood squirting has not been documented in the flat-tailed horned lizard (Sherbrooke 1990, *op. cit.*; Sherbrooke 1991. Amer. Midl. Natur. 126:187–195; Middendorf and Sherbrooke 1992. Copeia 1992:519–527; Sherbrooke, pers. comm.). Other mammals, including coyote (*Canis latrans*) and grasshopper mouse (*Onychomys torridus*) are known horned lizard predators (Munger 1986, *op. cit.*; Sherbrooke, pers. comm.).

On 29 November 1993, the U.S. Fish and Wildlife Service proposed to list *P. mcalii* as a threatened species pursuant to the Endangered Species Act of 1973, as amended (Federal Register 58:62624–62629).

We thank the reviewers of our draft manuscript. This work was supported by contracts from USDI Bureau of Land Management, Riverside, California, U.S. Army Corps of Engineers, Los Angeles District, and U.S. Department of Energy, to Frederick B. Turner, while the authors were employed as research assistants to Dr. Turner through a cooperative education program with Prescott College, Prescott, Arizona. We also thank Margaret H. Fusari, our former advisor and mentor at Prescott College.

(KLE): The Nature Conservancy, 212 E. Marcy St., Suite 200, Santa Fe, New Mexico, USA.

TARENTOLA MAURITANICA (Moorish Gecko). **BEHAVIOR**. *Tarentola mauritanica* is a small gekkonid lizard distributed throughout the Mediterranean Basin (Martínez-Rica 1974. P. Cent. pir. Biol. exp. 5:7–291; Mayol 1985. Rèptils i Amfibis de les Balears. Editorial Moll, Palma de Mallorca. 234 pp.). It is often the most abundant lizard at a site, showing marked anthropophilous behavior. Its activity is nocturnal, crepuscular, or both (Martínez-Rica 1974, *op cit.*; Rieppel 1981, *In* W. Böhme (ed.), Handbuch der Reptilien und Amphibien Europas, Echsen, Sauria I, Akademische Verlagsgesellschaft, Wiebaden, pp. 119–133). Nocturnal foraging activities center around artificial lights when available (Mayol 1985, *op cit.*, and pers. obs.), where this gecko captures mainly flying prey. *Tarentola mauritanica* is chiefly insectivorous (Rieppel 1981, *op cit.*), but small lizards are occasionally taken (Bauer 1990. Herpetol. Rev. 21(4):83–87; Salvador 1979. Doñana Acta Vert. 5:5–17).

During a survey of the herpetofauna of Minorca (Balearic Islands) in August 1988, we observed prey capture by *T. mauritanica*. Typical foraging behavior on the house walls near artificial lights involved a sequence of acts. First, the prey was detected from an ambush site where the gecko remained motionless. Second, the lizard approached slowly within 5 to 30 cm of the prey. Third, the attack typically was a charge (following Carpenter and Ferguson 1977, *In* C. Gans and D. W. Tinkle (eds.), Biology of the Reptilia, Vol. 7, Ecology and Behavior, pp. 335–403. Academic Press, New York.), a rapid rush towards the prey from a distance greater than the length of the lizard. We recorded 19 attacks from 19 different individuals of which 10 failed. In 15 attacks the lizards held their tails straight or only slightly turned to the side. These attacks were directed in all cases against small insects: moths (13 attacks),

alderflies (1 attack), and flies (1 attack). In the remaining four attacks, the lizards raised their tails during the slow approach, moving it laterally and sometimes with the distal portion of the tail slightly brought forward. The final charge was accompanied by increased vibration, shaking rapidly the tip of the tail. These four attacks were directed towards large moths; one was unsuccessful.

This is the first record of tail waving behavior as part of a prey capture tactic in gekkonid lizards (Salvador 1979, *op cit.*; Rieppel 1981, *op cit.*). Tail waving in general was described previously as precopulatory courtship behavior (Carpenter and Ferguson 1977, *op cit.*).

Within the context of prey capture, tail waving and vibration has been interpreted as a mechanism for distracting the prey's attention away from the lizard's head (Carpenter and Ferguson 1977, *op cit.*), or as caudal luring (Heatwole and Davison 1976. Herpetologica 32:332–336). Caudal luring has been described for several snake species and a pygopodid lizard. In some cases caudal luring is limited to juvenile individuals that possess brightly colored tails (Radcliffe et al. 1980. Bull. Maryland Herp. Soc. 16:19–22; Mushinsky 1987. *In* Seigel et al. (eds.), Snakes: Ecology and Evolutionary Biology, Macmillan Pub. Co., New York, pp. 302–334; Murray et al. 1991. Copeia 1991(2):509–516). Radcliffe et al. (1980, *op cit.*) proposed that caudal luring of *Boa constrictor* was a displacement activity. During slow motion approach, the inhibition of the tendency to move rapidly toward the prey is an important part of a successful prey capture and could result in a conflict that produces tail waving as a displacement activity (Radcliffe et al. 1980, *op. cit.*). The function of tail waving in *T. mauritanica* is unresolved and requires further observation.

These observations were made possible partially by grant PB90-0526-C02-01 from the Spanish Ministry of Science and Education.

Submitted by **VALENTÍN PÈREZ-MELLADO**, Department of Environmental Sciences and Natural Resources, University of Alicante, 03080- Alicante, Spain.

TROPIDURUS TORQUATUS (Collared Lizard). **DIET**. Lizards of the genus *Tropidurus* (Tropiduridae) prey on arthropods (Vanzolini et al. 1980. Rèpteis da Caatinga. Rio de Janeiro: Academia Brasileira de Ciências. 161 pp.). Although the genus *Tropidurus* is widespread (South America and the Galapagos Islands) and speciose (Rodrigues 1987. Arq. Zool., São Paulo 31(3):105–230), information on the diet of most species remains scarce, unknown, or is anecdotal and based on few individuals. *Tropidurus torquatus* is a diurnal lizard common to open areas of southeastern Brazil (Rodrigues 1987, *op. cit.*). Here we document the diet of 29 *T. torquatus* collected during August 1991, a month during the dry season. Field work was conducted at a "Restinga" (sandy habitats covered with herbaceous and shrubby vegetation that are common along the Brazilian coast) in the municipality of Linhares (19°18'S, 40°19'W) in the State of Espirito Santo, Brazil. We analyzed the stomach contents of 29 *T. torquatus* (range 34.0–81.0 mm SVL, mean = 61.1 mm ± 15.2), counted and estimated the volume of each prey item (following Schoener 1967. Science 155:474–477). *Tropidurus torquatus* has a generalized diet composed predominantly of arthropods, ants being the most frequent prey (Table 1). Lizards of the genus *Tropidurus* are sit-and-wait foragers (*sensu* Schoener 1971. Ann. Rev. Ecol. Syst. 2:369–404; Vanzolini et al. 1980, *op. cit.*). The diversity and high frequency of mobile prey in the diet of *T. torquatus* is consistent with such feeding behavior. Plant material (flowers only) in the stomachs of 38% of the lizards suggests that plants were not eaten by the lizard casually and may be an important food resource for *T. torquatus*.

We thank the Companhia Vale do Rio Doce for logistical support in the field and the CNPq for the grants (No. 84024089-9 to CFDR and No. 84023491-0 to HGB). Monique Van Sluys kindly revised the text.

TABLE 1. Number of items, volume (in mm^3) and frequency of each type of prey of *Tropidurus torquatus* in the restinga of the Reserva Florestal Vale do Rio Doce, Linhares, Espirito Santo (N = 29).

SERPENTES

BOIGA IRREGULARIS (Brown Tree Snake). **REPRODUCTION**. Clutch size in *Boiga irregularis* is not well documented. Shine (1991. Copeia 1991:120–131) discussed two clutches from Australia. Zwinenberg (1978. Aquarien. Terrian. Z 31:177–179) also reported clutch size. Despite high densities of *B. irregularis* on Guam, (Rodda et al. 1992. Pac. Sci. 46:46–57), no clutches have been reported, although captive snakes have deposited eggs (unpubl. data). I herein report on the first clutch of eggs found and successfully incubated of *B. irregularis* on Guam. On 30 June 1990, a *B. irregularis* (1295 mm SVL) was captured (Mangilao Municipality: Adacao) and placed in a glass jar. Between 0000 and 0600 h, on 6 July, the snake deposited eight eggs and was donated the following day to Guam Division of Aquatic and Wildlife Resources (DAWR). Eggs were removed and incubated at ambient

temperatures (daily range 25–30°C) on moist paper towels in a loosely closed, opaque plastic jar. Eggs (mean length 43.36 mm, width 22.96 mm) were adherent and formed a mass weighing 110.12 g. On 24 July, one egg was discolored, separated, and preserved. On 9 October, two eggs pipped and one snake emerged. On 10 October, the remaining six eggs were opened, containing dead, full-term embryos (N = 7, mean SVL = 272.43 mm, SD 12.42; mean mass = 5.29 g, SD 0.58). Incubation period was 94 days. These data are not entirely inconsistent with those presented by Shine (1991, *op. cit.*). Snakes the size of these neonates/embryos have never been collected on Guam, but snakes 330 to 350 mm SVL possess prominent umbilical scars (pers. obs.). However, snakes of this latter size range comprise less than 1% of snakes collected or observed by DAWR on Guam (N = ca. 2300, pers. obs.).

Reproduction in *B. irregularis* on Guam may be aseasonal (Fig. 1). Two females were necropsied with shelled oviductal eggs in June and October. Females with 42-43 mm long secondary follicles (probably just prior to shelling) have been recorded in January. Enlarged (≥ 30 mm length) secondary follicles have also been recorded in February, April, June, and October. These data suggest that shelled eggs are produced year-long on Guam. Shine (*op. cit.*) reported a highly seasonal component to reproduction of *B. irregularis* in Australia. There is little seasonal variation in temperature on Guam, but a marked wet/dry season is evident (Fritts et al. 1987. The Snake 19:51–58). Factors other than seasonal weather patterns may influence reproduction of *B. irregularis* on Guam.

Rebecca Hensley reviewed a draft of this paper. Research was supported by the Endangered Species Conservation Program, Project E4.

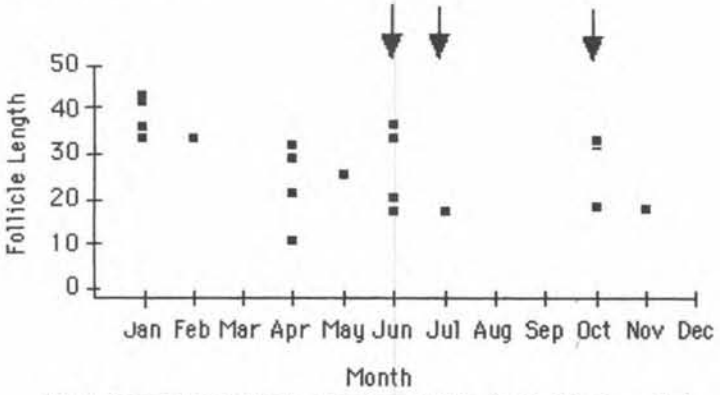

FIG. 1. Seasonal variation in secondary follicle size in *Boiga irregularis* from Guam. Data collected between 1984 and 1990. Arrows indicate months in which shelled eggs were found.

Submitted by **MICHAEL JAMES McCOID**, Division of Aquatic and Wildlife Resources, P.O. Box 2950, Agana, Guam 96910, USA. Present address: Caesar Kleberg Wildlife Research Institute, Texas A & M – Kingsville, Kingsville, Texas 78363, USA.

COLUBER CONSTRICTOR PRIAPUS (Southern Black Racer). **PREY**. On 29 July 1993 at 1750 h EST on a forest road near the eastern edge of the Apalachicola National Forest, Leon County, Florida, I was attracted by loud thrashing noises to a *Coluber constrictor priapus* (TL = 93 cm) actively manipulating its jaws around the head of a *Sistrurus miliarius barbouri* (TL = 41 cm). When I approached within 2 m, the racer attempted to retreat with its prey, which it subsequently dropped. Within 30 min the rattlesnake was responsive and looked as if it would recover fully.

Although *C. constrictor* is known to prey on many snakes including at least one pit viper, *Agkistrodon contortrix* (Fitch 1963. Univ. Kansas Publ. Mus. Nat. Hist. 15:351–468), this observation appears to be the first record of *C. constrictor* preying on *Sistrurus*.

I thank D. Bruce Means for his assistance and Dale R. Jackson for reviewing the manuscript.

CROTALUS HORRIDUS (Timber Rattlesnake). **LONGEVITY**. On 6 October 1954, a young male *Crotalus horridus* (TL = 55.9 cm) was brought to the biology laboratory of Louisiana College. It was estimated to be 12–18 months old. Feedings were limited to three or four per year. From 1954 to 1990 he was fed 125 times and consumed 58 mice, 3 "leather-winged" bats, 20 hooded rats, 75 gray rats, 76 white rats, 3 moles (Talpidae), 10 newborn rabbits, and 20 gerbils. Always when swallowing his prey he began to rattle.

When disturbed, a rattlesnake may spray venom like a cobra, accomplishing this by exhaling a sudden blast of air from the glottis against the poison as it comes from the fangs (Barbour 1926. Reptiles and Amphibians, Houghton Mifflin Co., Boston, Massachusetts, p. 44). During the 36 years this snake was carefully watched, no spraying of venom was ever observed.

After the snake reached 25 years of age it was no longer able to kill its prey, and was subsequently fed pre-killed food. Often it took two or three days to complete a feeding of several food animals. On 2 June 1991, he was found dead. The rattlesnake measured 1.77 m TL. He was preserved and placed in a museum jar for display in the laboratory, having lived in captivity for 36 years, 7 months, and 27 days.

Submitted by **CHARLES J. CAVANAUGH**, Professor Emeritus, Department of Biology, Louisiana College, Pineville, Louisiana, 71360, USA.

MICROPECHIS IKAHEKA (Small-eyed or Ikaheka snake). **OPHIOPHAGY**. The New Guinea endemic, *Micropechis ikaheka*, is a little known elapid which reaches 2.5 m TL and adopts a secretive, nocturnal, and semi-fossorial existence. The species is fairly common on Kar Kar Island, an active volcanic island in the Bismarck Sea 17 km NE Madang, Papua New Guinea. This note reports a case of predation on a boid, *Candoia aspera*, by *M. ikaheka*. A *M. ikaheka* (SVL = 670, TL = 770 mm) was captured by a plantation worker on 27 January 1993. Investigation of the snake's stomach contents revealed a partially digested *Candoia aspera* (SVL = 300, TL = 320 mm) that was swallowed head first. If *M. Ikaheka* habitually preys on *C. aspera*, the large population of the latter and several other potential prey species could in part account for the especially large population of *M. ikaheka* on Kar Kar Island in comparison with similar plantation locations on the mainland. Both specimens will be deposited in the British Museum (Natural History).

I thank Roger, Rosa, and Ian Middleton, Ilaiah Bigilale (National Museum of Papua New Guinea), Iamo, Ila, and Mick Raga (DEC), M. Jebb (Christensen Research Institute), and John Cheung (Island Airways). This work was funded in part by the Nuffield Department of Clinical Medicine, John Radcliffe Hospital, Oxford, England.

Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish

Nombres Científicos y Comunes en Ingles y Español de los Anfibios y los Reptiles de México

ERNEST A. LINER

with Spanish Translation by

José L. Camarillo R.

This exhaustive work is a complete listing of the 1,539 taxa that comprise the herpetofauna of Mexico. The author provides ready access to the common and scientific names of the 206 genera, 956 species, and 583 races of amphibians and reptiles found in Mexico, and includes the name of the describer(s) and the date(s) of publication for each. A must for anyone interested in Mexican herpetology. vi + 113 pages. ISBN 0–916984–32–X. 1994.

Prepublication price $9.00 for SSAR Members—after September 30, 1994 $12.00

Orders may be sent to Robert D. Aldridge, Department of Biology, Saint Louis University, St. Louis, Missouri 63103 USA

the habits of *Micropechis ikaheka* other than it is nocturnal and frequents damp forest, swampy ground, and coconut plantations where it preys on lizards, small mammals, and snakes. During a five month period, I collected 15 live *M. ikaheka* on Kar Kar Island, Madang Province, Papua New Guinea. The snakes ranged in size from < 300 mm to 1500 mm SVL. They were housed at the University of Papua New Guinea in groups of three in spacious wooden cages measuring 1.2 x 0.6 x 0.3 m, and were fed laboratory mice. On the morning of 10 August 1990, a female measuring 910 mm SVL (TL = 1040 mm) had eaten another female measuring 875 mm SVL (TL = 965). All three snakes in this cage were fed mice some days previously and the cannibalistic female had fed particularly well. The cannibalized female appeared in good health the previous evening.

I thank Roger and Rosa Middleton, Matthew Jebb (CRI), Phil and Brenda Willmott-Sharp, James Menzies (UPNG), and Mick Raga (DEC). This work was funded in part by a Christensen Research Institute Fellowship and the Nuffield Department of Clinical Medicine, John Radcliffe Hospital, Oxford, England.

NERODIA RHOMBIFER (Diamondback Water Snake). **ALBINISM**. In the summers of 1988 and 1989, two albino *Nerodia rhombifer* were captured at Reelfoot Lake, Tennessee. The 1988 specimen (adult, TL ca. 930 mm) was killed by a fisherman near Samburg, Obion County, Tennessee, and given to David Haggard, naturalist at Reelfoot Lake Slate Park. The 1989 specimen (juvenile, TL ca. 350 mm) was captured in Lake County, Tennessee. A photo of this specimen appeared in Burkett and Huggins (1993. J. Tennessee Acad. Sci. 68(1):32).

Dyrkacz (1981. SSAR Herp. Circ. 11, 31 pp.) reviewed albinism in amphibians and reptiles and listed the degrees of albinism. The specimens from Reelfoot Lake are classified as partial albinos with xanthophores, since both had a light yellow ground color with a white pattern of chain-like markings and pink eyes. We previously reported five amelanistic (without melanin) juveniles born to one female of this species from the St. Francis River bottoms of Greene County, Arkansas, approximately 60 km SW Reelfoot Lake (Burkett and Huggins 1985. Herpetol. Rev. 16:56).

Dyrkacz (*op. cit.*) reported albinism in two closely related species, *N. fasciata* and *N. sipedon*, but the only known instances of albinism in *N. rhombifer* are the two reported herein. The occurrence of aberrant colors in these two adjacent populations suggests possible gene flow across the Mississippi River Valley and the possibility of finding other abnormally colored specimens from this geographic area.

We thank C. Norvell, Tennessee Department of Conservation, for informing us about the first specimen, and the naturalists at Reelfoot Lake State Park for allowing the second specimen to be examined and photographed.

PYTHON MOLURUS BIVITTATUS (Burmese Python). **MOVEMENTS**. On 27 July 1992 in the village of Shui Hau, Lantau Island, Hong Kong, an old Chinese woman reported a "tai nam she" (literally "big belly snake," *P. m. bivittatus*) in her oven-sized, free-standing chicken coop. Apparently the snake had entered through a hole, eaten the two mature chickens within, and was unable to exit through the same hole. Extricated, the female python measured 2.7 m TL. The woman vigorously explained in Cantonese (though her pantomime was sufficient) that we could recover the chickens by holding the snake's head under water. Additional stimulus proved unnecessary; after it was removed from the coop the snake quickly regurgitated and the delighted old woman departed with the chickens.

On 31 July 1992, the snake was force-fed a L. L. Electronics two-stage transmitter (150 MHz) attached to a 1/4 wavelength antenna powered by a AA-sized lithium battery. We retained the snake overnight to ensure that the transmitter stayed inside and working. On 1 August at 1700 h the snake was released 170 m from the capture site east of the village.

The movements of the python were followed until 20 August from three stations to determine general position. On most days we directly approached the snake to examine the habitat occupied. In Fig. 1, the python's sequential positions are labeled with the number of days since capture. Snake locations were generally recorded during daylight hours (0600–2000 h) except a few positions which were recorded at night: 13b, 15a–c, and 17b (Fig. 1).

During the 24-day period the python's home range was 12.3 ha with a maximum linear dimension of 550 m (minimum convex

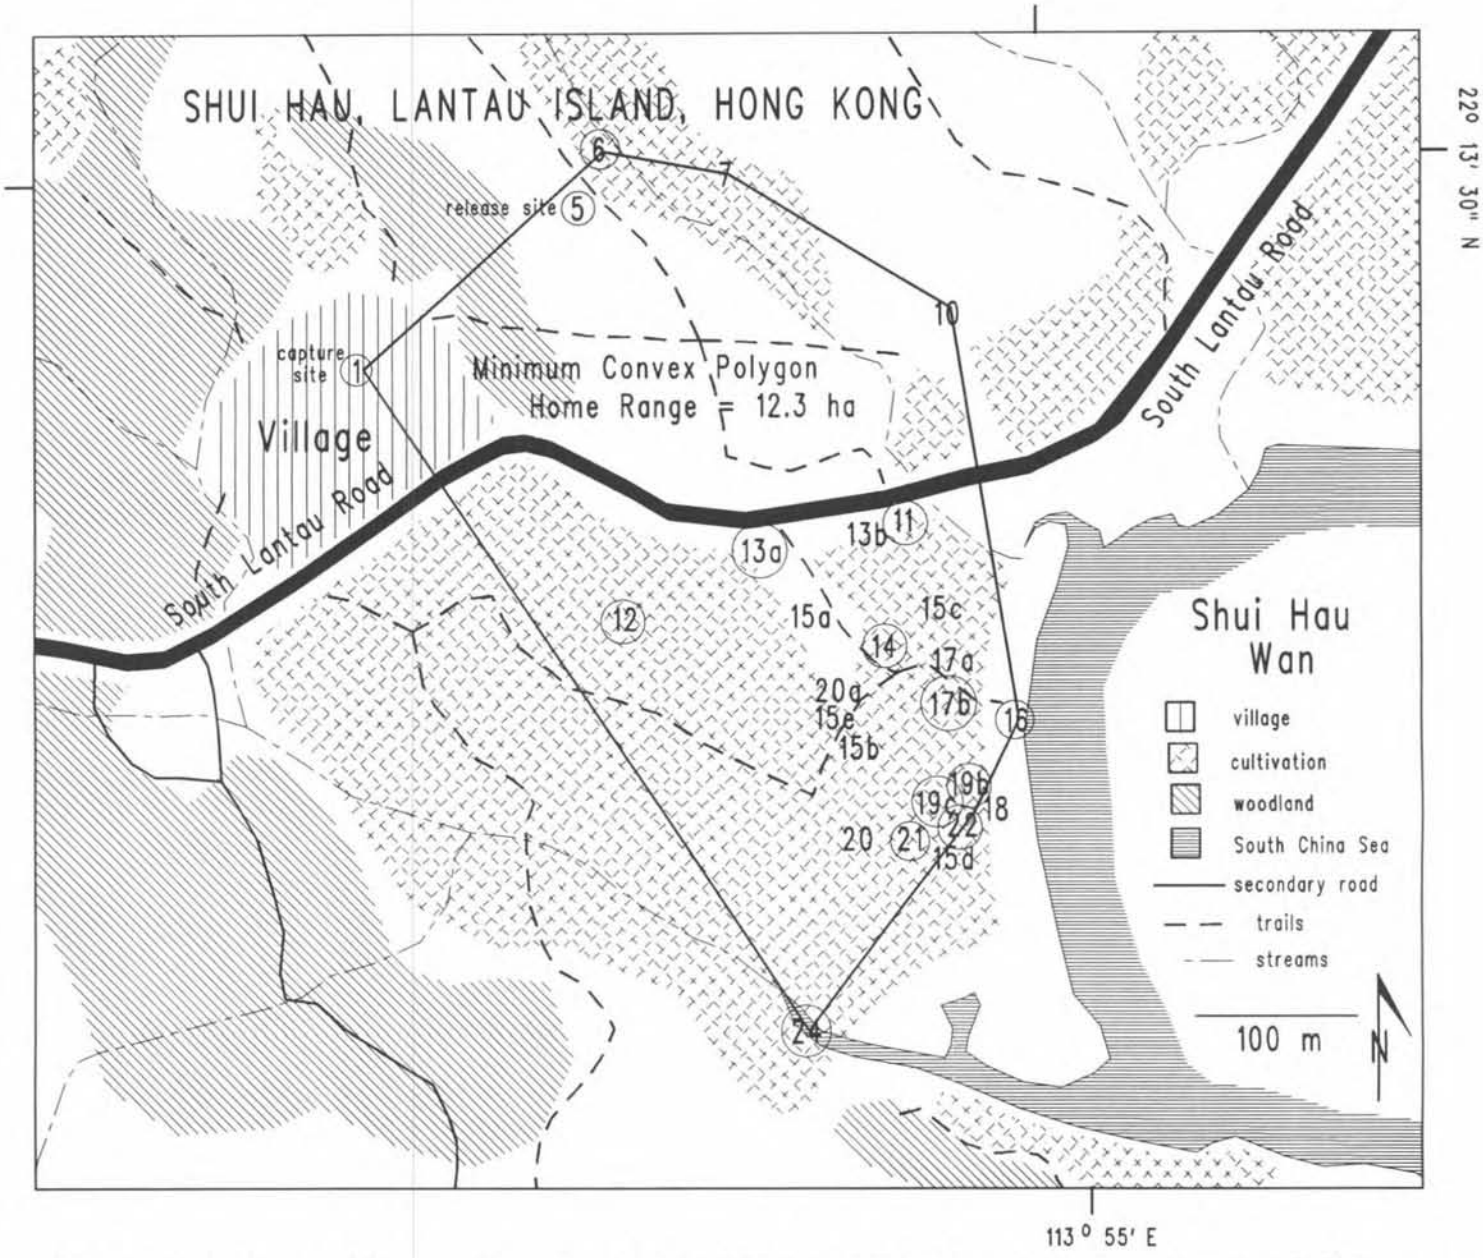

FIG. 1. MAP of the study area depicting sequential movements of a 2.7 m TL female *Python molurus bivittatus*. The polygon shows the snake's home range during the 20-day observation period. Unshaded areas represent scrubby vegetation or grassland. Numbers indicate the snake's sequential location by day of the study period. Letters indicate sequence of movements on a particular day. Circled positions were confirmed by direct approach and are accurate to within 10 m; uncircled positions were determined by telemetry fixes from three stations and are accurate to within 100 m.

polygon method; Mohr 1947. Amer. Midl. Nat. 37:223–249). On days 6 and 12, direct approach revealed the snake either completely or partly submerged in abandoned rice paddies. On three occasions (11, 13b, 14) daytime retreats were inside large rock piles or in vegetation near rock walls of cultivated fruit orchards. The snake spent the majority of tracking days (locations 16–22) near the beach in a dense *Pandanus* thicket.

Confirmed locations indicated that over the first few days after release (days 5–14), the snake ranged widely. We presume she was hungry on release as she had lost the meal of chickens from 27 July. On day 19, direct approach revealed the python had eaten something large. It made no long range movements until, between days 22 and 24, it moved southwest and passed the radiotag in a stream. The data suggest a cycle of wide ranging search for food, a period of limited movement during digestion, followed by elimination and a return to search behavior. Alternatively, the initial wide-ranging movements may have been an attempt to relocate portions of its home range because the snake was translocated on release.

Thanks to "chuk she lo" (snakecatchers) Glenn Mitchell, James Lazell, and James Conyers, and the radiotrackers and spotters: James Conyers, David Corsini, Daniel Freitas, Paul Gagne, III, Elizabeth Harris, Thomas Kinney, Bea Klepner, Timothy Loose, Richard Lutman, Glenn and Sally Mitchell, Betsy Olsen, John Rogers, Larry Ruotolo, Kerry Shered.

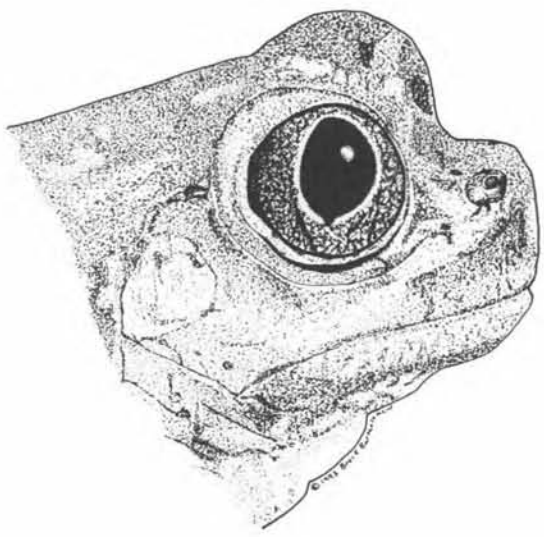
SIMOPHIS RHINOSTOMA (NCN). **DIET**. The two species of the little known colubrid snake genus *Simophis* range from southeastern Brazil to Paraguay, in southeastern South America (Peters and



Orejas-Miranda 1970. Bull. U.S. Nat. Mus. 297:1–347). *Simophis rhinostoma* attains about 80 cm TL, is terrestrial and diurnal, and inhabits savannah-like areas and secondary disturbed forests (Sazima and Abe 1991. Stud. Neotrop. Fauna Environ. 26:159–164). Although reported to prey on "small rodents and other small animals" (Amaral 1976. Serpentes do Brasil, Melhoramentos, São Paulo, 246 pp.), no substantiated data on food of *S. rhinostoma* seem available (Sazima and Abe, *op. cit.*). Here we report on gut contents of 12 snakes from several localities in the State of São Paulo, SE Brazil, housed in the collection of the Instituto Butantan, São Paulo (IB).

We found five snakes (393–682 mm SVL) with identifiable prey, all of them frog remains. Three we ascribed to the small (ca. 30 mm SVL) leptodactylid frog *Physalaemus cuvieri*, and the others were bones of small leptodactylids the same size as *P. cuvieri*. Estimated prey/predator mass ratio for *S. rhinostoma* ranged from 0.1 to 0.2. Feeding on relatively small prey is common for most colubrid snakes (Greene 1983. Am. Zool. 23:431–441). Seven snakes had insect remains in the hindgut, a frequent finding for frog-eating snakes (pers. obs.). *Physalaemus cuvieri* is nocturnal and terrestrial, hiding by day under stones or pieces of wood, and in ground crevices or holes (Bokermann 1962. Rev. Brasil. Biol. 22:391–399; pers. obs.). The wedge-shaped snout profile of *S. rhinostoma* seems well suited to forage for frogs in such shelters.

We found no evidence that *S. rhinostoma* preys on rodents (Amaral 1976, *op. cit.*). Rodent-eating snakes generally are either heavy, constricting, or poisonous (Greene 1983, *op. cit.*; Shine and Schwaner 1985. Copeia 1985:1067–1071). *Simophis rhinostoma* is a slender, non-poisonous snake with short and feeble teeth (pers. obs.) suited for small and unarmed prey such as frogs.

We thank O. A. V. Marques for expert advice and reading the manuscript, G. Puorto for access to the IB snake collection, J. P. Pombal Jr. for confirmation of the identity of frog remains, and the CNPq for financial support.

BUFO WOODHOUSII FOWLERI (Fowler's Toad). USA: NEW YORK: Suffolk Co: Fire Island Pines Marina, Harbor Walk. 14 June, 1993. Robert M. Price. RMP 35601. Adult male. Verified by Peter Warny, Long Island Science Museum. A total of 207 specimens were observed but not collected on the primary and secondary dunes of the Fire Island National Seashore between Water Island and Sunken Forest during the months of June, July, and August. The specimen collected was on private property, sitting under a harbor light at 2023 h, and had been noticed there on the previous evening. This is the first authenticated occurrence of the species on the Fire Island barrier beach in direct contact with salt spray. It is also the southernmost occurrence in Suffolk County. Based on the number of subadult toadlets observed and the calling males throughout the summer, it seems certain that the species is established and breeding in Fire Island Pines.

Southern Illinois University at Carbondale Department of Zoology Collection (SIUC H-4511). Confirms unvouchered published report (Hurter 1893, Trans. St. Louis Acad. Sci. 6(11):251–261; Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **STEVEN J. TAYLOR** and **JEAN K. KREJCA**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901, USA.

PSEUDACRIS TRISERIATA MACULATA (Boreal Chorus Frog). USA: WYOMING: Johnson Co: W 1/4 Sec. 3, T41N, R82W. 19 August 1993. Kris Harold Johnson. Verified by George T. Baxter. University of Wyoming Zoological Museum (UW 623). First township record; first county record west of Powder River (Baxter and Stone 1985, Amphibians and Reptiles of Wyoming. Wyoming Game and Fish Dept., 137 pp.).

Submitted by **KRIS HAROLD JOHNSON, GREGG L. KURTZ**, and **RICHARD A. OLSON**, Department of Range Management, and **THOMAS D. WHITSON**, Department of Plant, Soil, and Insect Sciences, University of Wyoming, Laramie, Wyoming 82071-3354, USA.

RANA CATESBIANA (Bullfrog). USA: ILLINOIS: St. Clair Co: Dieciseis Tigrinum Pit (a cave). 22 June 1993. Jean K. Krejca and Steven J. Taylor. Verified by Ronald A. Brandon. Southern Illinois University at Carbondale Department of Zoology Collection (SIUC H-4510). County record (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **STEVEN J. TAYLOR** and **JEAN K. KREJCA**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901, USA.

RANA PIPIENS (Northern Leopard Frog). USA: COLORADO: Las Animas Co: Salt Creek, 13 km N and 5 km W Trichera, Sec. 22, T33S, R60W. 5 September 1992. L. J. Livo. Verified by P. S. Corn. UCM Herpetology Color Slide 75. Extends range ca. 80 km E of nearest record for this species (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Div. Wildl., Denver, 131 pp.). Specimen was one of several newly metamorphosed individuals along creek; surrounding area is occupied by *Rana blairi* (Hammerson, *op. cit.*), although none was seen at this locality.

Submitted by **LAUREN J. LIVO**, 1215 South Osceola Street, Denver, Colorado 80219, USA.

RANA PSALTES (Harpist Frog). TAIWAN: NANTOU CO: Lienhwachih, ca. 6 km N Yuchih (23°55'32"N, 128°53'02"E). 26 August 1993. Wen-hao Chou. Verified by W. S. Huang. National Museum of Natural Science (NMNS 2369). First record for Taiwan (Lue et al. 1990, Wildlife Data Bank of Taiwan, (1) Amphibians (II). Ecol. Res. Report 8, Council of Agric., 157 pp.). This species was described by Kuramoto (1985, Herpetologica 41:150–158) from Yaeyama group of the Ryukyu Islands.

Submitted by **WEN-HAO CHOU**, Department of Zoology, Division of Collection and Research, National Museum of Natural Science, Taichung, Taiwan 40419, Republic of China.

SCINAX NASICA (NCN). ARGENTINA: PROVINCIA DE BUENOS AIRES: Baradero, Estancia "El Retoño" (33°48'S, 59°30'W). 20–22 March 1993. Verified by G. R. Carrizo. Museo Argentino de Ciencias Naturales "Bernardino Rivadavia" (MACN 34612–18). First record for Province, 260 km SW from the southernmost record given by Gallardo (1982, Mus. Cs. Nats. Extra Nueva Serie 128:65–75).

Submitted by **JULIAN FAIVOVICH**, Division Herpetologia, Museo Argentino de Ciencias Naturales "Bernardino Rivadavia", Casilla Postal 220, Sucursal 5, 14005 Buenos Aires, Argentina.

SPEA BOMBIFRONS (Plains Spadefoot). USA: WYOMING: Fremont Co: SW 1/4 Sec. 25, T3N, R5E. 29 May 1993. Kris Harold Johnson. Verified by Joseph T. Collins. University of Wyoming Zoological Museum (UW 624, color slide). Photographed and released. First township record and first record west of Wind River in Fremont County; most southwestern record for Wyoming (Baxter and Stone 1985, Amphibians and Reptiles of Wyoming. Wyoming Game and Fish Dept., 137 pp.).

Submitted by **KRIS HAROLD JOHNSON**, **GREGG L. KURTZ**, and **RICHARD A. OLSON**, Department of Range Management, and **THOMAS D. WHITSON**, Department of Plant, Soil, and Insect Sciences, University of Wyoming, Laramie, Wyoming 82071-3354, USA.

TESTUDINES

APALONE SPINIFERA (Spiny Softshell). USA: WISCONSIN: Brown Co: Suamico River, U.S. Rt. 41 crossing (Sec. 23, T25N, R20E). 7 July 1991. P. W. LaBarge. Milwaukee Public Museum (MPM P361). Adult female caught by angling with nightcrawler for bait; Duck Creek, Village of Howard. 30 July 1992. Collector unknown; specimen given to D. Hartman. Milwaukee Public Museum (MPM P414). Juvenile. Both specimens verified by G. S. Casper. Extend known distribution in the Green Bay system two drainages north from previously reported population in the Fox River (Cochran 1991, Herpetol. Rev. 22:64); suggest possibility that *A. spinifera* occurs along the intervening western shoreline of Green Bay proper.

Submitted by **PHILLIP A. COCHRAN**, Division of Natural Sciences, St. Norbert College, DePere, Wisconsin 54115, USA.

DERMATEMYS MAWEI (Central American River Turtle). BELIZE: ORANGE WALK DISTRICT: Blue Creek, ca. 12 km NW of Blue Creek Village. 10 September 1993. Steven G. Platt. Verified by Tony Garel. Nine turtles (7 females, 2 males) taken alive in trammel net. Two males deposited in Belize Zoo. Voucher photographs deposited in Clemson University Vertebrate Collection (CUSC 1069, 1070). First record for Rio Bravo Headwaters (Moll 1986, Biol. Conserv. 35:87–96); extends range ca. 25 km from the New River Basin.

Submitted by **STEVEN G. PLATT**, Department of Biological Sciences, Clemson University, Clemson, South Carolina, 29634-1903, USA.

MACROCLEMYS TEMMINCKII (Alligator Snapping Turtle). USA: LOUISIANA: East Baton Rouge Parish: Bayou Duplantier, ca. 1.0 km E of Stanford Avenue. 24 January 1988 and 7 August 1988. Verified by Stanlee Miller. Shells and skeletal material deposited in Clemson University Vertebrate Collection (CUSC 964, 769). New parish record; fills hiatus between adjacent parishes (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge. 300 pp.; Pritchard 1989, The Alligator Snapping Turtle: Biology and Conservation. Milwaukee Pub. Mus. 104 pp.).

Submitted by **STEVEN G. PLATT** and **LANCE W. FONTENOT**, Department of Biological Sciences, Clemson University, Clemson, South Carolina 29634-1903, USA.

STERNOTHERUS ODORATUS (Common Musk Turtle). USA: ILLINOIS: Kane Co: Max McGraw Wildlife Foundation, 1.05 km W of Rt 25 & 2.5 km S of Rt 72 (42 4'36"N, 88 16'12"W). 21 October 1993. V. J. Santucci and A. K. Wilson. Verified by R. A. Brandon. Southern Illinois University at Carbondale (SIUC R-2580). Smith (1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298) shows a literature record but no voucher for this species in the county; new county record.

Submitted by **ALLAN K. WILSON**, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA.

TRACHEMYS SCRIPTA (Slider). TEXAS: Hamilton Co: jct Rt. 281 and Leo River. 7 March 1992. Kelly J. Irwin, Travis W. Taggart, and Adam Sweetman. Verified by Joseph T. Collins. KU 221256. County record (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M Univ. Press, College Station, Texas, 434 pp.). Collected under Texas Parks and Wildlife Permit SPR-0691-414.

Submitted by **KELLY J. IRWIN**, 2218 West Second Street, Topeka, Kansas 66606, USA, **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA, and **ADAM SWEETMAN**, 220 Rainbow Lake Road, Wichita, Kansas 67235, USA.

LACERTILIA

CALOTES VERSICOLOR (Indian Tree Lizard). SINGAPORE: KENT RIDGE: National University campus. 13 May 1988, K. L. Yeo. Verified by Kelvin Lim. Zoological Reference Collection, National University of Singapore (ZRC 2.3393). New locality record. Geographic range previously reported as India across to southern China and down to northern states of West Malaysia (Boulenger 1890, Fauna of British India, Taylor and Francis, London, 541 pp.; 1912, Vertebrate Fauna of the Malay Peninsula: Reptilia & Batrachia. Taylor and Francis, London, 294 pp.).

Boulenger (1912, *op. cit.*) and Smith (1935, Fauna of British India. Reptilia and Amphibia. Vol. 2. Sauria. Taylor and Francis, London, 440 pp.) maintained that the species was absent from the southern states of West Malaysia. Apart from an isolated record from Sumatra (de Rooij 1915, Reptiles of the Indo-Australian Archipelago. Vol. 1. E. J. Brill, Leiden, 384 pp.) based on a badly damaged specimen, no other records existed to suggest that the geographic range extended further south than the upper region of West Malaysia. Obviously introduced, the species has established

itself rapidly in landscaped and open grounds throughout Singapore.

Submitted by **L. M. CHOU**, Department of Zoology, National University of Singapore, 10 Kent Ridge Crescent, Singapore 0511.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). USA: ILLINOIS: Madison Co: Poag, SE 1/4 NW 1/4 SE 1/4 Sec. 13, T4N, R9W. 19 May 1993. D. A. Landes. Verified by R. A. Brandon. Southern Illinois University at Carbondale (SIUC R-2598). County record (Smith 1961, The Amphibians and Reptiles of Illinois. Bull. Illinois Nat. Hist. Surv. 28(1):1–298).

Submitted by **SCOTT R. BALLARD**, Illinois Department of Conservation, Division of Natural Heritage, 4521 Alton Commerce Parkway, Alton, Illinois 62002, USA, and **DAVID A. LANDES**, Biology Department, Belleville Area College, 2500 Carlyle Road, Belleville, Illinois 62221-5899, USA.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). USA: INDIANA: Knox Co: Oaktown Quadrangle, SW 1/4 Sec. 24, T5N, R10W, abandoned sand and gravel pit with moderate ground cover. 6 June 1993. Verified by Sherman A. Minton. Indiana State Museum 71.7.324. Although there are historic records for Knox and Posey counties (Burt 1931, A Study of the Teiid Lizards of the Genus *Cnemidophorus* with Special Reference to their Phylogenetic Relationships. U.S. Natl. Mus. Bull. 154:1–286) to the best of our knowledge these represent the first recent specimens collected in southwestern Indiana.

Submitted by **DENNIS R. BROWN**, 8439 Trotter Road, Camby, Indiana 46113, USA, and **JARROD HARVEY**, 208 North Gillespie Street, Greencastle, Indiana 46105, USA.

CROTAPHYTUS COLLARIS (Collared Lizard). USA: ILLINOIS: Johnson Co., Ferne Clyffe State Park. New state record. A juvenile (SIUC R-2491) was captured on 22 October 1992 by Eric Johns, and a basking adult female was photographed by one of us (AKW) on 20 August 1993; a photographic print is catalogued as SIUC R-2597. Two adults had been sighted at the same locality by SIUC graduate students on 26 June 1993. Because none had been found previously despite much field work in the bluffs of southwestern Illinois, the possibility that this population may have been introduced cannot be ruled out. Smith (1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28(1):1–298) postulated they might occur in Monroe County, and they are known from three bordering counties in Missouri (Johnson 1989, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.; Powell et al. 1993, Missouri Herpetol. Assoc. Newsl. 6:7–26).

Submitted by **RONALD A. BRANDON** and **ALLAN K. WILSON**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901, USA.

EUMECES OBSOLETUS (Great Plains Skink). TEXAS: McMullen Co: 9 mi S Tilden. 11 March 1992. Kelly J. Irwin, Travis W. Taggart, and Adam Sweetman. Verified by Joseph T. Collins. KU 221252. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, Texas, 434 pp.). Collected under Texas Parks and Wildlife Permit SPR-0691-414.

Submitted by **ADAM SWEETMAN**, 220 Rainbow Lake Road, Wichita, Kansas 67235, USA, **KELLY J. IRWIN**, 2218 West Second Street, Topeka, Kansas 66606, USA, and **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

SCELOPORUS OLIVACEUS (Texas Spiny Lizard). USA: TEXAS: Jones Co: Lueders, Lueders City Park. 24 March 1985. L. A. Fitzgerald. UNM 44566–7. Verified by Allan Landwer. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Press. 434 pp.).

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado, 80309-0334, and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA.

SCINCELLA LATERALIS (Ground Skink). USA: MISSOURI: Franklin Co: Meramec State Park. 16 June 1950. Collected by Milton Weller. Dallas Museum of Natural History Reptile Collection (DMNH 1867). Verified by Tom R. Johnson. New county record; partly fills in northeastern Missouri range (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **THOMAS VANCE**, Biology Department, Navarro College, Corsicana, Texas 75110, USA.

SCINCELLA LATERALIS (Ground Skink). TEXAS: Webb Co: 4 mi W Bruni. 9 March 1992. Kelly J. Irwin, Travis W. Taggart, and Adam Sweetman. Verified by Joseph T. Collins. KU 221253. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, Texas, 434 pp.). Collected under Texas Parks and Wildlife Permit SPR-0691-414.

Submitted by **ADAM SWEETMAN**, 220 Rainbow Lake Road, Wichita, Kansas 67235, USA, **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA, **KELLY J. IRWIN**, 2218 West Second Street, Topeka, Kansas 66606, USA.

SERPENTES

BOTHROPS MOOJENI (Brazilian Lancehead). BRAZIL: MATO GROSSO: 2 km N Porto Jofre on Rodovia Transpantaneira. 16 September 1993. Wolfgang Wüster and Stephen Pierini. Verified by Miguel Trefaut Rodrigues. Instituto Butantan (IB 55112). First record from Poconé and confirms predication (Campbell and Lamar 1989, Venomous Reptiles of Latin America. Comstock, Ithaca, New York. 425 pp.) of its presence within the Pantanal. Specimen was found DOR in a zone of permanently dry higher ground with cerrado vegetation.

Submitted by **WOLFGANG WÜSTER**, Department of Zoology, University of Aberdeen, Tillydrone Avenue, Aberdeen AB9 2TN, Scotland, United Kingdom, **STEPHEN PIERINI**, 93 Putnoe Lane, Bedford, MK41 9AH, England, United Kingdom, and **GIUSEPPE PUORTO**, Laboratório de Herpetologia, Instituto Butantan, Avenida Vital Brasil 1500, CEP 05503-900 São Paulo - SP, Brazil.

CROTALUS VIRIDIS CERBERUS (Arizona Black Rattlesnake). USA: COLORADO: Arapahoe Co: ca. Sec. 30, T4S, R64W. 6 October 1993, Ivan Littlejohn. Verified by H. M. Smith. UCM Zoology Color Slides 78–79. Specimen represents an escapee or introduction near the fringe of an urban area. Another rattlesnake collected at the same site was a normal *Crotalus viridis viridis*, the subspecies native to the area (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Div. Wildl., Denver. 131 pp.).

Submitted by **LAUREN J. LIVO**, 1215 South Osceola Street, Denver, Colorado 80219, USA, and **DAVID CHISZAR**, Department of Psychology, Campus Box 345, University of Colorado, Boulder, Colorado 80309, USA.

FARANCIA ABACURA REINWARDTII (Western Mud Snake). USA: LOUISIANA: Red River Parish: 16 km S Coushata on US Rt. 84. 3 June 1978. Collected by Terry L. Hibbitts. Dallas Museum of Natural History (DMNH 4975). Verified by Harold A. Dundee. County record (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge. 300 pp.).

Submitted by **THOMAS VANCE**, Biology Department, Navarro College, Corsicana, Texas 75110, USA.

GYALOPION QUADRANGULARE (Desert Hooknose Snake). USA: ARIZONA: La Paz Co: crossing paved road late in the evening near Salome (ca. 33°42'30"N, 113°30'W). 12 July 1993. Joseph Casada, Jose Rosado, and Eugene Trescott, Jr. (UAZ 52001, photographs by Manny Rubio). Verified by Howard Lawler. New county record; extends range ca. 250 km from vicinity of Nogales, Santa Cruz County.

Submitted by **EUGENE TRESCOTT, JR.**, Natural History Associates, P. O. Box 1477, Inverness, Florida 34451-1477, USA.

LAMPROPELTIS TRIANGULUM AMAURA (Louisiana Milk Snake). USA: TEXAS: Ellis Co: DOR, Walker Creek Road N FMR 85 and E Ennis. 6 May 1992. Collected by Nancy Davis. Preserved specimen collection at Navarro College (NC 1992. 5. 6. 1S). Verified by Pat Johnson. New county record; partly fills hiatus in north central Texas range (Dixon 1987, Amphibians and Reptiles of Texas. 434 pp.; Williams 1988, Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*. Milwaukee Publ. Mus. 176 pp.).

Submitted by **THOMAS VANCE**, Biology Department, Navarro College, Corsicana, Texas 75110, USA.

LIOCHLOROPHIS VERNALIS BLANCHARDI (Smooth Green Snake). USA: COLORADO: Teller Co: Rampart Range Road at East Plum Creek, 2.4 km (airline) S Douglas County line, 0.5 km (airline) E El Paso County line. Early July 1979. Russell P. DeFusco. Verified by Richard L. Holland. UCM Color Slide 77. County record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver. 131 pp.).

Submitted by **RUSSELL P. DeFUSCO**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado, 80309-0345, USA, **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

MASTICOPHIS TAENIATUS TAENIATUS (Desert Striped Whipsnake). USA: COLORADO: Moffat Co: Dinosaur National Monument, 15 km N Zenobia Peak (Sec. 16, T9N, R102W). 1 September 1991. L. J. Livo. Verified by P. S. Corn. UCM Herp. Color Slide 64; Dinosaur National Monument, Pot Creek along bank of Green River. 12 June 1982. D. E. Wilson and S. J. Martin. Verified by P. S. Corn. (U. S. Fish and Wildlife Service Biological Survey Collection, Ft. Collins, Colorado, BS/FC 2007). Specimens extend range ca. 13 and 24 km N of previous records in Colorado (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Div. Wildl., Denver, 131 pp.).

Submitted by **LAUREN J. LIVO**, 1215 South Osceola Street, Denver, Colorado 80219, USA.

OPHEODRYS VERNALIS (Smooth Green Snake). USA: WISCONSIN: Door Co: Chambers Island, within 80 m of NE shoreline. 6 September 1993. J. F. Blahnik. Verified by G. S. Casper. Milwaukee Public Museum (MPM P413). New county record (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Publ. Mus. 205 pp.); first record from any Lake Michigan island (Long 1993, Bull. Chicago Herpetol. Soc. 28:214–218). That this specimen was not an isolated waif is suggested by a sighting three years previously (M. Blahnik, pers. comm.).

Submitted by **JAMES F. BLAHNIK** and **PHILLIP A. COCHRAN**, Division of Natural Sciences, St. Norbert College, DePere, Wisconsin 54115, USA.

SALVADORA GRAHAMIAE (Mountain Patchnose Snake). TEXAS: Hamilton Co: just SE jct Rt. 281 and Bosque River. 7 March 1992. Kelly J. Irwin, Travis W. Taggart, and Adam Sweetman. KU 221254; McMullen Co: 22 mi S Tilden. 8 March 1992. Kelly J. Irwin, Travis W. Taggart, and Adam Sweetman. KU 221257. Both verified by Joseph T. Collins. County records (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, Texas, 434 pp.). Collected under Texas Parks and Wildlife Permit SPR-0691-414.

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA, **KELLY J. IRWIN**, 2218 West Second Street, Topeka, Kansas 66606, USA, **ADAM SWEETMAN**, 220 Rainbow Lake Road, Wichita, Kansas 67235, USA.

SISTRURUS MILIARIUS STRECKERI (Western Pigmy Rattlesnake). USA: LOUISIANA: De Soto Parish: Dolet Hills, 8 km SE Mansfield. October 1973. Collected by Terry L. Hibbitts. Dallas Museum of Natural History (DMNH 4418) Verified by Harold Dundee. New county record; partly fills hiatus in western Louisiana range (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge. 300 pp.) and confirms earlier claim of expected occurence in De Soto Parish (Strecker and Frierson 1926, Contrib. Baylor Univ. Mus. 5:1–10).

Submitted by **THOMAS VANCE**, Biology Department, Navarro College, Corsicana, Texas 75110, USA.

STORERIA DEKAYI (Brown Snake). TEXAS: McMullen Co: S Tilden on Rt. 16 at Nueces River. 8 March 1992. Kelly J. Irwin, Travis W. Taggart, and Adam Sweetman. Verified by Joseph T. Collins. KU 221255. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, Texas, 434 pp.). Collected under Texas Parks and Wildlife Permit SPR-0691-414.

Submitted by **KELLY J. IRWIN**, 2218 West Second Street, Topeka, Kansas 66606, USA, **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA, **ADAM SWEETMAN**, 220 Rainbow Lake Road, Wichita, Kansas 67235, USA.

Two Anoles New To Broward County, Florida

Since 1987, we have been aware of a release site for several exotic reptiles in Broward County, Florida. This site, now a horse stable, was formerly a reptile importer's warehouse. Here we report on two species of anoles that have become established at this location. Vouchers were collected by the authors, verified by C. Guyer, and deposited in the Auburn University Museum (AUM), as follows:

ANOLIS CHLOROCYANUS (NCN). Broward Co: Parkland, N of Holmberg Road. 14 September 1991. Seven individuals were observed and two were collected (AUM 33672–73). First United States record (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed., Houghton Mifflin Co., Boston, Massachusetts. 450 pp.; Wilson and Porras 1983, The Ecological Impact of Man on the South Florida Herpetofauna. Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9, 89 pp.).

CTENONOTUS (ANOLIS) CYBOTES (Largehead Anole). Broward Co: Parkland, N of Holmberg Road. 14 September 1991. More than 50 individuals were observed and four were collected (AUM 33674–77). New county record (Conant and Collins, *op. cit.*; Wilson and Porras, *op. cit.*).

Both species of lizards appeared to be restricted to an area no greater than 5 ha. *Ctenonotus cybotes* greatly outnumbered *A. chlorocyanus* and utilized a wider array of perch types than did *A. chloracyanus*. *Anolis chlorocyanus* was found only on smooth barked trees and buildings while *C. cybotes* perched on different types of trees, buildings, piles of lumber, and fence posts.

Submitted by **BRIAN P. BUTTERFIELD**, Department of Zoology and Wildlife Science, 331 Funchess Hall, Auburn University, Alabama 36489-5414, USA, **WALTER E. MESHAKA, JR.**, Archbold Biological Station, P. O. Box 2057, Lake Placid, Florida 33852, USA, and **ROGER L. KILHEFNER**, 9050 NW 28 Street, Apt. 109, Coral Springs, Florida 33065, USA.

County Records For Florida Amphibians And Reptiles

A review of Florida specimens of amphibians and reptiles in the Louisiana State University Museum of Natural Science (LSUMZ) has revealed a number of county records for that state. These records are based on comparisons with distributional data presented by Ashton and Ashton (1988a, 1988b, 1991) and records subsequently published in the Geographical Distribution section of Herpetological Review. Identity of all specimens was verified by either Douglas A. Rossman, David A. Good, or Anna L. Bass.

PSEUDOBRANCHUS STRIATUS (Broad-striped Dwarf Siren). Bradford Co: U.S. Rt. 301 at Santa Fe River Swamp. 27 October 1991. P. Moler. LSUMZ 54370, 54371.

SIREN LACERTINA (Greater Siren). Pasco Co: ca. 4.8 km E New Port Richey. 7 August 1970. W. Neill, L. Hope, R. Thomas. LSUMZ 22009-22015.

AMPHIUMA MEANS (Two-toed Amphiuma). Madison Co: I-10 at Hixtown Swamp, 9.9 km E U.S. Rt. 221. August 1991. P. Moler, B. Mansell, C. Abercrombie. LSUMZ 54227. Washington Co: U.S. Rt. 90, 7.7 km E Choctawatchee River. 24 September 1991. P. Moler. LSUMZ 54224.

NOTOPHTHALMUS VIRIDESCENS (Eastern Newt). Bay Co: Pine Log State Forest, Sec. 18, T1S, R16W. 19 September 1991. J. Palis. LSUMZ 54215-54223. Bradford Co: U.S. Rt. 301 at Santa Fe River Swamp. 27 October 1991. P. Moler. LSUMZ 54374. Lake Co: Fla. Rt. 50, ca. 2.2 km E Sumter County line. 28 March 1991. P. Moler, B. Mansell. LSUMZ 53226-53228. Madison Co: I-10, ca. 9.6 km E U.S. Rt. 221. 14 April 1991. P. Moler, C. Schwalbe, H. Adams. LSUMZ 53245-53247. Sumter Co: Sec. 10, T20S, R22E and Sec. 34, T19S, R22E. March 1991. D. Stevenson, D. Crowe. LSUMZ 53213-53225.

AMBYSTOMA OPACUM (Marbled Salamander). Gulf Co: 4.8 km ENE Wewahitchka. 4 May 1967. R. Blaney, K. Relyea. LSUMZ 25219, 25220.

EURYCEA QUADRIDIGITATA (Dwarf Salamander). Holmes Co: Wright's Creek, 9.6 km S jct. Fla. Rt. 2 on Fla. Rt. 79. 6 May 1967. R. Blaney, K. Relyea. LSUMZ 52143.

HYLA AVIVOCA (Bird-voiced Treefrog). Gulf Co: Dead Lakes region near Wewahitchka. March 1968. L. Wilson. LSUMZ 41338.

HYLA FEMORALIS (Pine Woods Treefrog). Holmes Co: 4.8 km E Bonifay. 2 September 1950. G. Lowrey, Jr. LSUMZ 1847-1851.

HYLA SQUIRELLA (Squirrel Treefrog). Osceola Co: 28.8 km S St. Cloud on Fla. Rt. 523. 3 May 1970. L. Wilson. LSUMZ 29317.

PSEUDACRIS CRUCIFER (Spring Peeper). Escambia Co: Brushy Creek, 3.4 km W end of Rt. 97, Enon. 6 February 1967. R. Blaney, K. Relyea. LSUMZ 15869.

ALLIGATOR MISSISSIPPIENSIS (American Alligator). Leon Co: ca. 3.2 km W Iamonia Tall Timbers Research Station. 3 June 1967. Boettcher and Buskirk. LSUMZ 18947.

CHELYDRA SERPENTINA (Snapping Turtle). Pasco Co: New Port Richey. 20 August 1970. R. Thomas. LSUMZ 22016.

KINOSTERNON BAURII (Striped Mud Turtle). Pasco Co: ca. 6.4 km NW Hudson. 15 August 1970. R. Thomas. LSUMZ 22004.

KINOSTERNON ODORATUM (Common Musk Turtle). Pasco Co: ca. 8 km NE New Port Richey. 13 September 1968. R. Thomas. LSUMZ 27992.

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). Wakulla Co: St. Marks Wildlife Refuge. 18 April 1959. D. Rossman. LSUMZ 9146.

PSEUDEMYS FLORIDANA (Cooter). Gulf Co: FL 71, 14.1 km S Wewahitchka. 4 May 1967. R. Blaney, K. Relyea. LSUMZ 24787.

GOPHERUS POLYPHEMUS (Gopher Tortoise). Charlotte Co: no further data. 1961. C. Harper. LSUMZ 43344.
APALONE FEROX (Florida Softshell). Liberty Co: Owl Creek. 27 July 1952. R. Beter. LSUMZ 6175.

OPHISAURUS ATTENUATUS (Slender Glass Lizard). Levy Co: 16 km NE Lebanon Station. 8 June 1960. M. Fouquette, D. Rossman. LSUMZ 13674. 14.4 km NE Lebanon Station. 8 June 1960. D. and N. Rossman. LSUMZ 33928.

OPHISAURUS COMPRESSUS (Island Glass Lizard). Franklin Co: St. George Island, 4.3 km W Bridge. 30 March 1968. R. Blaney. LSUMZ 21827. Osceola Co: 15.8 km N Yeehaw Jct. 9 April 1959. D. Rossman. LSUMZ 6587.

OPHISAURUS VENTRALIS (Eastern Glass Lizard). Duval Co: Jacksonville, ca. 9.6 km W St. Johns River. 1 April 1985. R. Lawson, B. Mansell, P. Frank, J. Cole. LSUMZ 44911, 44912. Holmes Co: Bonifay. Fall 1952. D. Grant. LSUMZ 5906. Orange Co: Orlando. 10 November 1968. L. Wilson. LSUMZ 42181.

Noteworthy Distributional Records For Some Snakes From Jersey And Madison Counties, Illinois

Specimens documenting the following distributional records were all obtained DOR by the author along Illinois Route 100, and were deposited at the Illinois Natural History Survey (INHS). Identifications were confirmed by L. E. Brown, Department of Biological Sciences, Illinois State University.

ELAPHE VULPINA VULPINA (Western Fox Snake). Jersey Co: NW 1/4 Sec. 13, T6N, R12W, 3.2 km NW Elsah Road. 7 October 1993. INHS 11006; NE 1/4 Sec. 26, T6N, R11W, 1.1 km NW Piasa Creek. 7 October 1993. INHS 11007; NW 1/4 Sec. 20, T6N, R11W, at Elsah Road. 16 October 1993. INHS 11009; SW 1/4 Sec. 21, T6N, R11W, 2.2 km SE Elsah Road. 22 October 1993. INHS 11010. Madison Co: SE 1/4 Sec. 4, T5N, R10W, at Hop Hollow. 8 October 1993. INHS 11008. New county records. Previously reported from Jerseyville, Jersey Co., by Smith (1961) based on a single specimen (INHS 1317) collected in 1936. Specimens reported here from Jersey and Madison counties extend range a total of 27 km S of Jerseyville record. They further confirm the existence of disjunct populations in southern Illinois and indicate that they occupy a considerable geographic area.

LAMPROPELTIS GETULA HOLBROOKI (Speckled Kingsnake). Jersey Co: S 1/2 Sec. 12, T6N, R13W, at Deer Plain Ferry. 8 October 1993. INHS 11000. New county record and extends range 94 km WSW from closest Illinois record (Smith 1961).

NERODIA ERYTHROGASTER FLAVIGASTER (Yellowbelly Water Snake). Madison Co: SE 1/4 Sec. 4, T5N, R10W, 3.2 km SE Clifton Terrace Road. 8 October 1993. INHS 11103; NW 1/4 Sec. 4, T5N, R10W, 2.4 km SE Clifton Terrace Road. 6 October 1993. INHS 11104; NW 1/4 Sec. 31, T6N, R10W, 1.6 km NW Clifton Terrace Road. 8 October 1993. INHS 11100; NW 1/4 Sec. 32, T6N, R10W, 0.3 km SE Clifton Terrace Road. 7 October 1993. INHS 11099; NW 1/4 Sec. 32, T6N R10W, 0.8 km SE Clifton Terrace Road. 7 October 1993. INHS 11098 and INHS 11105; NW 1/4 Sec. 4, T5N, R10W, 2.6 km SE Clifton Terrace Road. 17 October 1993. INHS 11108. New county record.

NERODIA RHOMBIFER RHOMBIFER (Diamondback Water Snake). Madison Co: NE 1/4 Sec. 31, T6N, R10W, 0.3 km NW Clifton Terrace Road. 7 October 1993. INHS 11056. Confirms county record not documented by specimens reported by Hurter (1911).

*NERODIA SIPEDON SIPEDON (Northern Wate*r Snake). Madison Co: NW 1/4 Sec. 31, T6N, R10W, 1.1 km NW Clifton Terrace Road. 8 October 1993. INHS 11071 and INHS 11072; NW 1/4 Sec. 32, T6N, R10W, 0.2 km SE Clifton Terrace Road. 8 October 1993. INHS 11075; NW 1/4 Sec. 32, T6N, R10W, at Clifton Terrace Road. 21 October 1993. INHS 11089. NW 1/4 Sec. 10, T5N, R10W, 4.2 km SE Clifton Terrace Road. 17 October 1993. INHS 11091. New county record.

PITUOPHIS MELANOLEUCUS SAYI (Bullsnake). Madison Co: NW 1/4 Sec. 4, T5N, R10W, 1.9 km SE Clifton Terrace Road. 22 October 1993. INHS 11001. Confirms county record not documented by specimens reported by Stull (1940) and indicates that disjunct populations in southwestern Illinois noted by Smith (1961) are still extant.

REGINA GRAHAMII (Graham's Crayfish Snake). Madison Co: SE 1/4 Sec. 4, T5N, R10W, 3.1 km SE Clifton Terrace Road. 8 October 1993. INHS 11046; SE1/4 Sec. 4, T5N, R10W, at Hop Hollow. 16 October 1993. INHS 11051; SE1/4 Sec. 32, T6N, R10W, 1.4 km SE Clifton Terrace Road. 17 October 1993. INHS 11054. Confirms county record not documented by specimens reported by Hurter (1911). Jersey Co: NE 1/4 Sec. 13, T6N, R12W, at Chautauqua Road. 7 October 1993. INHS 11043; NE 1/4 Sec. 15, T6N, R12W, 0.2 km E Grafton. 7 October 1993. INHS 11044; S1/2 Sec. 12, T6N, R13W, at Deer Plain Ferry. 8 October 1993. INHS 11045; NE1/4 Sec. 27, T6N, R11W, 5.4 km NW Clifton Terrace Road. 16 October 1993. INHS 11047-11048; NE1/4 Sec. 26, T6N, R11W, 5.8 km SE Elsah Road. 16 October 1993. INHS 11049; NE1/4 Sec. 28, T6N, R11W, 2.4 km SE Elsah Road. 16 October 1993. INHS 11050; NW 1/4 Sec. 25, T6N, R11W, 0.3 km SE Piasa Creek. 16 October 1993. INHS 11052; SE1/4 Sec. 20, T6N, R11W, 0.5 km SE Elsah Road. 21 October 1993. INHS 11053; SE1/4 Sec. 18, T6N, R11W, 4.8 km SE Grafton. 17 October 1993. INHS 11055. Previously reported by Smith (1961) from a single specimen (INHS 1751) collected in 1942. Jersey Co. records reported here confirm continued existence of species in this now highly developed area.

THAMNOPHIS PROXIMUS PROXIMUS (Western Ribbon Snake). Jersey Co: NW 1/4 Sec. 27, T6N, R11W, 3.7 km SE Elsah Road. 24 October 1993. INHS 10999. Confirms county record not documented by specimens reported by Garman (1892).

Hemidactylus mabouia As An Established Member Of The Florida Herpetofauna

In the United States, *Hemidactylus mabouia* is known from the southeastern region of mainland Florida (Butterfield et al. 1993) where it is common on buildings and nearby trees. In the keys, *H. mabouia* has been reported from Crawl Key (Lawson et al. 1991) and Bahia Honda (Gunther et al. 1993). Here, we report eight new records of *H. mabouia* in the Florida Keys and comment on its presence and establishment in Florida. All specimens will be deposited in the United States National Museum (USNM).

Monroe Co: Key West, corner of South and Elizabeth Streets. 21 September 1993. USNM 217879. Female, 60 mm. Collected on lit wall of hotel. Six additional specimens were collected on the walls of lit buildings in town.

Monroe Co: Stock Island, Moose lodge. 23 September 1993. USNM 217895. Female, 61 mm. Collected on lit wall of building. Fourteen additional specimens collected on lit buildings.

Monroe Co: Middle Torch Key. 22 September 1993. USNM 217880. Male, 59 mm. USNM 217881. Immature, 41 mm. Collected on lit buildings. Other individuals observed but not collected.

Monroe Co: Sunshine Key. 21 September 1993. USNM 217878. Male, 58 mm. Collected on lit building. Other individuals observed but not collected.

Monroe Co: Lower Sugar Loaf Key, West Circle. 21 September 1993. USNM 217875. Male, 67 mm. USNM 217876. Male, 46 mm. Collected on lit buildings. Other individuals observed but not collected.

Monroe Co: Big Pine Key, Visitor Center. 21 September 1993. USNM 217877. Male, 67 mm. Collected on lit building. Other individuals observed but not collected.

Monroe Co: Fat Deer Key, Key Colony Beach. 21 September 1993. USNM 217882. Female, 62 mm. Collected on lit building. Six additional specimens collected on nearby lit buildings. Other individuals observed but not collected.

Monroe Co: Plantation Key, Audubon Building. 21 September 1993. USNM 217889. Immature, 41 mm. Three additional specimens collected on the lit building. Other individuals observed but not collected.

The above records are suggestive of continuous distribution through the chain of keys. At our collecting sites, we counted between three and twenty individuals on buildings. Hatchlings were present at nearly all sites and, at some sites they were numerous (5–10).

Based on the ubiquity and widespread distribution of this species in southern Florida, we believe that *Hemidactylus mabouia* should be considered a firmly established member of the Florida herpetofauna. Key West and Miami were two locations which illustrated the strong colonization ability of *H. mabouia* under favorable conditions. During our evening searches on Key west, we found only one *H. turcicus* and three *H. garnotii*. At the time of Duellman and Schwartz's (1958) study, *H. garnotii* was unknown in Key West, however, *H. turcicus* was well established although not nearly as abundant as we have found *H. mabouia* (W. E. Duellman, pers. comm., 20 October 1993). The near absence of the once common *H. turcicus* was in stark contrast to the large number of *H. mabouia*, a close relative and a possible ecomorph of *H. turcicus*. This observation is suggestive of species displacement or, for unknown reasons, species replacement by *H. mabouia* and represents succession in exotic herpetofauna.

Unlike Key West, Duellman and Schwartz (1958) found few *Hemidactylus turcicus* in Miami. We were unable to find any *H. turcicus* in Miami, but *H. mabouia* was well established and at some sites very numerous and in syntopy with *H. garnotii*.

Presently, *H. mabouia* is the most successful of the three introduced hemidactylines known to occur on the Florida Keys and is rapidly dispersing throughout southern mainland Florida.

The sudden appearance of numerous thriving colonies suggests to us that this species was established much earlier than first detected by Lawson and colleagues (1991) and/or was recently introduced to multiple sites. Because we found this species to be abundant within its continuous range but spotty at northernmost locations, we suggest that both occurred. Introductions especially to Miami and the Florida Keys are quite probable from the agriculture and foliage trade of Brazil and Puerto Rico where *H. mabouia* is also an established exotic (Schwartz and Henderson 1985). Indeed, our most populated site is along the port of Miami near Miami International Airport. In this likely scenario, multiple introductions have been taking place and will continue to do so over time and at more than one location thereby increasing the probability of successful colonization and perhaps recolonization. If this is true, the Bahamian to Crawl Key connection suggested by Lawson and colleagues (1991) could also be attributed with other known target areas in the Caribbean and, in some instances, easily go the other way.

Acknowledgments.— We thank Joseph T. Collins for his comments regarding this ms.

Two Turtles New To The Florida Keys

While trapping *Kinosternon baurii* on Stock Island, we collected two species of emydid turtles previously unreported from the lower Florida keys (Lazell 1989; Wilson and Porras 1983). The turtles were collected in a roadside ditch with wire basket traps. Specimens were verified by James L. Dobie and deposited in the Auburn University Museum (AUM). Collections were made under Florida Game and Fresh Water Fish Commission permit WX93162 issued to J. B. Hauge. The records are:

DEIROCHELYS RETICULARIA CHRYSEA (Florida Chicken Turtle). Monroe Co: Stock Island Junior College Road. 23 September 1989. AUM 33633.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). Monroe Co: Stock Island, Jr. College Road. 24 September 1993. AUM 33634.

These records most probably are the result of pet turtles being intentionally released or escaping from their owners. Several people in the Key West area have an interest in turtles and are known to keep them as pets (R. W. Ehrig, pers. comm.). At present, we are unable to determine if breeding populations of either species occur at this site because only one individual of each species was collected. No other individuals of either species were observed at this site by us. Because we have no evidence of breeding populations of either species at this site, we suggest that other investigators use the records with caution when assessing the geographic distribution of these turtles.

BOOK REVIEWS

Biology of the Pitvipers. Edited by Jonathan A. Campbell and Edmund D. Brodie, Jr. 1992. Selva, P.O. Box 5213, Tyler, Texas 75712, USA. 467 pages, Hardcover. US $75.00. ISBN: 0-9630537-0-1.

There is, of course, no phenomenon such as carrying capacity in knowledge, but in *Biology of the Pitvipers* one can see more diverse approaches to the study of the biology of these snakes than ever before, more elegant solutions to an increasing number of problems, and the rise of new and fascinating questions. This book is the outcome of the Symposium on Pitviper Biology at the University of Texas at Arlington, 17–19 November 1989. The 30 papers by 50 herpetologists range from 5 to 30 pages in length. Twelve of the papers focus on single species, four are on the generic level, twelve on the whole subfamily Crotalinae, and two deal with the entire family Viperidae. The book covers a number of different subjects such as systematics, evolution, natural history, behavior, snakebite, and conservation.

Well corroborated phylogenies of Neotropical pitvipers are presented by Crother and co-workers and by Werman. Besides minor printing errors, Crother et al. do an excellent job of reconstructing the phylogenetic systematics and biogeographic history of the palm-pitvipers, genus *Bothriechis*. Werman is likewise convincing in his treatment of the phylogeny of the genus *Bothrops*, and partly resolves the relationships in this "old" group which now includes taxa referred to *Bothrops, Bothriechis, Porthidium, Atropoides* (and *Cerrophidion* Campbell and Lamar 1992). This is one of very few papers in the entire volume that focuses on South American taxa.

The phylogenetic study by John Cadle treats the entire family Viperidae (although the Viperinae is not well represented in the taxa sampled). This preliminary assessment of albumin evolution in vipers presents some surprising (and exciting) results including the position of *Azemiops* as the sister taxon to Crotalinae (or parts thereof). As emphasized by Cadle, care must be taken when making phylogenetic interpretations due to the generally conservative nature of viperid albumins. Cadle questions the recent generic splitting of *Bothrops* in the absence of comprehensive phylogenetic studies. To some extent such phylogenies have been presented by Crother et al. and Werman in this volume.

Sherman Minton uses radial immunodiffusion of albumins in an attempt to resolve relationships within the Crotalinae. There seems to be a pattern of hidden evolutionary species within *Crotalus* that should be further resolved. The ID (Index of Deviation) used demonstrated differences approaching species level between *Crotalus v. viridis* and *C. v. concolor* (the latter also having a high toxicity with neurotoxic components in its venom: Rael et al., this volume). As demonstrated by other studies in this volume the patterns of relationship between New and Old World *Agkistrodon* are still not fully resolved. The degree of difference of *Calloselasma* serum albumin is pronounced, approaching plasma of some non-viperid snakes, and is worthy of additional studies. The phylogenetic divergence of *Calloselasma* is also demonstrated by Densmore and Rael (this volume).

Another unresolved problem is *Sistrurus*, which Minton finds to be an unnatural group. However, Lillywhite and Smits (this volume) report that "the vast majority of blood flow perfusing the anterior tracheal lung may come from either left or right branches of the pulmonary artery (right in . . . *Agkistrodon*, mostly left in *Crotalus*, mixed in *Sistrurus*)." If "mixed" here means from both left and right side there are definitely interesting phylogenetic implications.

The fragmentary distribution and supposed unnatural taxonomy of *Crotalus lepidus* is further demonstrated by Rael and co-workers. This species shows a taxonomic pattern similar to the European *Vipera ammodytes*, with a number of "substratum races" and several more or less generally accepted subspecies. For practical reasons we need a practical taxonomy which may come into conflict with certain species concepts (e.g., cladistic species; see Otte and Endler 1989). External morphology yields a phenetic taxonomy which is available to anyone, while phylogenetic methods reveal evolutionary history. Additional approaches, like this one on venoms, may help to solve this dilemma. The viperine snake *Echis carinatus* (sensu lato), surprised researchers by its variable venom that showed both intra- and inter-population differences (e.g., Latifi 1978). Although not properly resolved, "*E. carinatus* s.l." seems to be composed of several sympatric or parapatric species (Cherlin 1990; Gasparetti 1988; Joger 1984; Leviton et al. 1992).

According to Knight et al., *Agkistrodon bilineatus taylori* is the sister taxon to *A. contortrix*, and the eastern and western populations of *A. piscivorous* are differentiated near the species level. *Agkistrodon* seems to be polyphyletic which again raises the question of whether *Gloydius* should be recognized for Asian *Agkistrodon*. The authors take no definite stand on this matter.

Additional phylogenetic and biogeographic papers include a study by Dorcas on *Crotalus lepidus* and *C. triseriatus* that elegantly resolves the systematic position of *C. t. aquilus* and one by Barker presenting a convincing reconstruction of the phylogeny of the evolutionary lineages within *C. willardi*, based on cladistic analyses of both morphological and allozyme data.

The study by Harry Greene on the ecological and behavioral context for pitviper evolution is an interesting and unconventional approach to the evolution of pitvipers that relies on the reconstruction of past phenotypes and adaptive scenarios. Behavioral and adaptive strategies of the Viperidae as a whole are examined with the aim of explaining the rise of pitvipers. Great insight is demonstrated in various aspects of viper biology although details for some taxa can be added, e.g., the sidewinding locomotion used by *Vipera latastii* in the sand dunes of southern Spain; the exclusively orthopteran feeding behavior by most *V. ursinii*; the presence of brightcolored ventral tail tips in almost all *Vipera*; the existence of a new aquatic, fish-feeding *Agkistrodon* in Mongolia (N. Orlov, pers. comm.). I like this kind of approach as a complement to more traditional analyses of evolutionary history. The supposed shared derived feature of tail vibration for *Azemiops feae* and crotalines supports the phylogenetic results of Cadle. Patterns of reproductive systems could be used in a more substantial way (e.g., Schuett, this volume) to analyze evolutionary history. Greene is of the opinion that the first crotalines were small, terrestrial snakes. Perhaps fossils, important clues as mentioned in his introductory section, could have been used for verifying size of early crotalines.

Several papers focus on pitviper morphology and physiology. Alan Savitzky describes the development of maxillary and prefrontal bones in crotalines, and their role in the placement of the pit organs, the important synapomorphy that characterizes pitvipers. The cardiovascular physiology of viperid snakes in general and Crotalinae in particular is discussed by Lillywhite and Smits. In particular the small heart, low blood pressure, and heavy body of these snakes prohibit upright posture, and affect resource utilization in viperid snakes. Arboreality is given as an example, a limitation also pointed out by Greene in his evolutionary approach. In this otherwise excellent description of viperid anatomy the authors have introduced a few errors: the statement that *Vipera palaestinae* is a pitviper (p. 147) is a lapsus, and the statement that the saccual lung terminates at the posterior margin of the kidneys in *Vipera* is incorrect. In *Vipera berus* (pers. obs.) and *V. aspis* (Lecuru-Renous and Platel 1970), for example, it ends cranial to the anterior margin of kidney.

A number of reproductive strategies and traits that have evolved in the Viperidae have been brought into focus by Schuett, Duvall

et al., and others. One aspect of pitviper reproduction is the capacity for sperm storage and its role in the timing of courtship and internal fertilization. A good part of Schuett's work deals with the categorization of spermatogenic and follicular cycles and mating periods in temperate vipers. Type III spermatogenesis (vernal) is common in Viperinae but rare in Crotalinae (except in *Crotalus r. ruber* and *C. viridis oreganus*). Schuett suggests that long term sperm storage might be plesiomorphic within the Crotalinae, a hypothesis that has yet to be demonstrated conclusively. Also unresolved are the reproductive patterns of tropical pitvipers. Do they exhibit sperm storage? What triggers ovulation? Is the time for ovulation fixed (as in temperate Viperidae)? The limited observations by Schuett on *Agkistrodon bilineatus* do not provide a clear answer. An adequate explanation for type I reproductive cycles and long term sperm storage also remains elusive. Hypotheses relating mating in summer (when males are dispersed and require a long time to search for mates) to type II follicular yolking cycles in *C. viridis*, seem plausible. A similar pattern can be seen in the European *Vipera berus*, with its type III (vernal) spermatogenic cycle and spring mating (post-shedding), where yolking takes place during the spring (type I). A question that is raised is whether yolking is correlated with feeding. In *V. berus* it is dependent on past feeding (correlated with fat-body maxima). Schuett correctly stresses the importance of long-term studies to solve the questions surrounding sperm storage, potentially multiple matings, etc.

Most papers on pitviper biology are based on temperate species. However, Sazima describes the natural history of the tropical *Bothrops jararaca*. It is not clear from his study how the data were collected (no "methods" section), how many snakes were used, or how many search hours were spent under different conditions. During the 2.5 years of investigation, 122 specimens were used in the seasonal activity analysis, but only 91 in the daily activity analysis. In the latter group only seven animals were observed during daytime, yet 28 animals were observed basking, etc. Still Sazima presents much interesting information, but several questions arise. Does the long pregnancy period also include female sperm storage? What factors trigger ovulation? To what extent has man affected population density by supporting additional prey species (*Rattus norvegicus* and *Mus musculus*)? To what degree can man utilize the jararaca as a controller of such pests? Unfortunately, the black and white photos accompanying this paper are far too small to adequately display their information content effectively.

For obvious reasons natural history studies may be of two kinds. If there is already a large body of knowledge available the author can penetrate rather deeply into the subject. The studies of *Crotalus horridus* are of this kind, and thus put a number of specific questions into focus. The other type of natural history work deals with taxa, perhaps rare or occurring in some remote region, for which little, often anecdotal information is available. The study by C. J. McCoy and Ellen Censky on the biology of *Porthidium yucatanicum* is clearly of this kind. This is a preliminary but very informative study about a taxon for which virtually no biological data were previously available. Similarly, Campbell and Solorzano provide a detailed and informative analysis of the biology of *Porthidium godmani*. The feeding biology is compared not only to size, seasonal variation, and habitat, but also between the two distribution areas of this taxon: Guatemala/El Salvador and Costa Rica/Panama. The high percentage of arthropods as prey is unusual in adult vipers but also occurs in *Vipera ursinii* and *V. latastii*. With respect to reproductive behavior, this species exhibits some features (e.g., male bites the female) that are more reminiscent of colubrids than temperate viperids. The obvious difference in morphology between southern and northern populations is interesting. The authors attribute this to the more frequent appearance of plesiomorphic character states at the periphery of the species' range, but the pattern of differences in prey utilization, female reproductive potential, and birth dates between Isthmian and Nuclear Central American samples, also demonstrated by the authors, suggests that additional studies are necessary.

The autecology of a few species has been studied in more detail and *Crotalus horridus* has been the main target in two such papers. The works of William Brown and William Martin are impressive for their long-term approaches. In general these kind of studies are very important for conservation purposes, in revealing hibernacula, summer areas, movements, home ranges, etc. Brown's studies on *C. horridus* have revealed a number of similarities with European *Vipera berus*. Differences are later emergence and higher number of females observed in the spring and more males observed in late summer. These can certainly be referred to the different reproductive systems in pitvipers and most viperines, with type I male cycle and associated Type II FY female cycle (Schuett, this volume) in *C. horridus* (late summer-autumn mating period) and the IIB male cycle in *V. berus* (spring mating). Martin comes to essentially the same conclusions in his impressive field study of *C. horridus*, with a slight delay of fall ingress dates. Martin has used a large number of snakes (N = 5926) in a truly longterm study (17 years), and with conservation in his mind ("sampling was nondestructive"). Although parts of his large volume of data could be somewhat condensed, it makes fascinating reading. Sixty percent of the juveniles survive the first winter but only 39% survive the first year. Martin believes that this results from failure to find adequate hibernacula, or from predation. But, of 333 observations in fall at hibernacula, 140 (42%) were young-of-the-year, whereas only 52 (3.3%) of 1566 spring observations were newborns. Thus, juvenile death in the hibernacula could be another factor. The application of telemetric and chemical ecological approaches to this well-studied population would be very rewarding.

The single largest paper in this volume concerns *Crotalus cerastes*. Timothy Brown and Harvey Lillywhite undertake a detailed behavioral study of individual specimens. It is an informative analysis although too lengthy, and the long, detailed, time-controlled behavior of a single snake becomes difficult to interpret when the clock suddenly goes backwards (p. 290). The paper was obviously planned to be published long ago, as evidenced by the lack of more recent references. The field work was performed during 1967–1969, and only three references (2.8%) are from the ten years prior to publication. Much has happened, especially in reproductive biology theory in recent years (e.g. Duvall et al. and Schuett in this volume). Interestingly, the noted increase in activity prior to rain is a phenomenon that also occurs in many Eurasian vipers (e.g., *Vipera dinniki* in the Caucasus, pers. obs.). However, the comment that European adders (*Vipera*) defend territories (p. 306) is probably a misunderstanding somewhere along the line. Adders defend only reproductive females and combat is frequent and a normal part of the reproductive behavior. Combat may perhaps function as a spacing mechanism between male sidewinders as mentioned by the authors, but the presence of a reproductive female definitely counteracts this. In *Vipera berus* spacing takes place after the mating period, not during it.

A comparison with the study by Secor (this volume) of the same species from the same area raises some interesting points. The movement distances reported are about equal in the two papers (monthly mean trackway length in July was 126.8 m according to Brown and Lillywhite; 128.3 as a combined mean during the activity season according to Secor) even though some variation between sexes and seasons in the two studies can be noted. But in size of the home range the two studies differ dramatically. According to Brown and Lillywhite home range sizes are 25–100 ha; according to Secor 14.7 ha.

Weldon et al. review the chemical ecology literature of crotaline snakes, and focus on four issues: the importance of skin lipids in water balance; the wide spectrum of pheromone use, in particular

juvenile scent trailing and mate attraction; chemicals in predator-prey interactions and in combination with body-bridging (a phenomenon characteristic of the Crotalinae but not verified in the Viperinae); and the secretions of the paired cloacal scent glands. It is an interesting approach that raises a number of questions. Field experiments are necessary for verifying theoretical assumptions as concluded by Duvall and co-workers in their paper "Pitviper mating systems: Ecological potential, sexual selection and microevolution." This is a theoretical approach to patterns of sexual selection in pitvipers in general, based on empirical studies of *Crotalus viridis*. In contrast to *Vipera berus*, *C. viridis* has a prolonged mate-searching polygyny system, characterized by late summer/autumn mating period and dispersed females, with sexual selection apparently acting on males. In the adder, females wait out the frequent male combats before giving access to the dominant (largest) male in the established hierarchy. Three important forces act in sexual selection on male rattlesnakes: (a) increased mate persuasion efficacy, (b) increased length of the mating season, and (c) decreased average mate cycling time. In the adder (b) is rather short, (c) may be long due to combats and female waiting behavior. The adder is involved in intensive combats during mating. According to Duvall et al. multiple matings and multiple paternity is expected to reduce the intensity of sexual selection on males, with less pronounced male-male competition. I share the opinion that multiple paternity is normally a rare phenomenon in the adder.

Hibernation biology is the focus in several studies, including the work Sexton et al. who conclude that soil thermal reversals dictate the denning behavior. The 38th north parallel appears to separate snakes using underground, communal dens from those using temporal refugia or having more or less active winter behavior. Their work raises a number of additional questions worth considering. How do the different reproductive strategies (spring mating as in European Viperinae or late summer-autumn mating as in North American Crotalinae) fit into this behavior? Are there methods other than scent tracking for snakes to locate suitable dens at distance? The proposed long distance heat sensing hypothesis is an interesting idea.

Barbara Savitsky examines piscivory in captive cottonmouths and found an ontogenetic shift from feeding on live fish in the young to carrion feeding in adults. The cottonmouth is one of a few very well-studied species of viperids and is therefore suitable for testing such hypotheses. The laboratory study is well performed and available field observations (although sometimes anecdotal) seem to support her results, but experimental studies in the lab should be supported by experimental field studies.

By statistically analyzing the relationship between rate of tongue-flicking and strikes versus nonstrikes in successful prey location Chiszar and co-workers found it possible to separate ambushers from chasers. The cottonmouth is shown to have more of a chasing behavior, in line with the study by Savitsky on feeding behavior (this volume). This is a continuation of an impressive series of work within the same field that Chiszar and associates have produced during a number of years (it is also Hobart Smith's 1,000th paper!). Empirical studies are often necessary in unknown fields, but when an experimental approach can be added a deeper understanding can be achieved. The studies of Chiszar and coauthors are excellent examples of simple but relevant experiments and tests within this field, and this paper is largely a synopsis of several of these studies.

Venoms and their effects have been studied from different perspectives and for different purposes. Hayes and co-workers investigated the mass of venom injected by prairie rattlesnakes. Among other results, LD 50 tests have shown that the prairie rattler injects 320 times the lethal dose into rodent prey. About 32% of available venom is injected at one strike. It would have been interesting to know the amount of venom their series of rattlers had expended in defensive strikes.

The sidewinder is an excellent target species for evaluating movement and home range size because movement patterns are revealed by trackways in the sand. Secor's paper together with the review of telemetric methods by Reinert, in which home range estimation methods are also evaluated, provides a good introduction to this subject. Our current telemetric studies within the Viperinae (*Macrovipera lebetina* complex) have benefited much from studies based on its North American ecological equivalents amongst *Crotalus*.

Dart et al. present an illuminating review of pitviper envenomation that makes dramatic and instructive reading. The authors claim that a snake that has been handled before it strikes exhibits more aggressive biting behavior and injects more venom, although this is not clearly demonstrated. For snake bites there are a number of household remedies employed around the globe that are more or less effective for "curing" snake bites. Hardy reviews some more current first aid measures that are in use against venomous snakes including pitvipers. He evaluates and accepts the efficacy of the Extractor vacuum pump but not the stun gun electroshock method. He further dismisses incision, constricting bands or tourniquets, cooling, and compression wrapping. It seems that nothing should be done except resting until reaching a hospital. However, first aid treatment is obviously important if properly performed, as illustrated in the chapter by Dart et al. (above). Although perhaps peripheral to the focus of the paper, I would like to have seen an evaluation of cortisone, antihistamine, and adrenaline as field equipment. These have been used against bites of vipers in Eurasia with good results. Shock is considered as a great threat and an adrenalin inhalator in the field kit could save lives.

Jacobsen and Gaskin review the problems of paramyxoviral infections and stress the risk of spreading infections to rare local taxa from captive-bred releases, as exemplified by the Aruba Island rattlesnake propagation program.

Our knowledge of pitvipers, as evidenced in this volume, is highly skewed towards certain taxa. *Crotalus horridus* is the subject of the discussion on 67 different pages whereas 54 taxa are only mentioned on pages 421–422 in the "The future of pitvipers" by Greene and Campbell. Many of these are Asian forms of which we have almost no knowledge for estimating threats or conservation needs. The future of pitvipers is of course of great concern and the time lag between scientific knowledge and practical conservation steps is problematic. The only *Bothriechis* presently included in CITES is *B. schlegelii*, the first-described and most wide ranging of the seven species, a situation that is also true for Eurasian vipers. Further, the authors stress problems with the non-biological aspects of traditional taxonomic approaches (biological versus evolutionary species concepts), which is sometimes a result of conflicts between taxonomists. A complaint is made that many attractive species are still not on CITES. I fully agree with this complaint, but it must be kept in mind that it is the researchers of these snakes who must first demonstrate the conservation need and, at least to some extent have the responsibility to bring the issue to the attention of regional or national officials in charge. Greene and Campbell identify 80 pitviper species as vulnerable and point out the need for additional scientific studies as vitally important in their conservation.

Comparatively little work has focused on Asian and South American pitvipers. This is a rather natural bias as the symposium was held in United States, and most participants were Americans studying the biology of American pitvipers. The symposium has resulted in an excellent publication focusing on American pitviper biology, touching briefly on the Eurasian representatives on its way. This publication answers many of the questions raised regarding pitviper biology, and demonstrates that there are many more to be dealt with in the future, even in North America.

During a comparatively short period three weighty volumes dealing with pitvipers have appeared (*Snakes of the Agkistrodon*

Complex by Gloyd and Conant; *The Venomous Reptiles of Latin America* by Campbell and Lamar; and the symposium volume under review here). The first will stand as a key reference for a certain group within the pitvipers and the second for a certain geographical region. This book will definitely serve as the focal reference in pitviper evolutionary biology in its broad sense and as such it should have lasting value.

Iguanas: A Guide to Their Biology and Captive Care, by Fredric L. Frye, B.Sc., D.V.M., M.Sc., CBiol, FIBiol, Fellow, Royal Society of Medicine, and Wendy Townsend. 1993. Krieger Publishing Company, Krieger Drive, Malabar, Florida, 32950, USA. ISBN 0-89464-695-8, 145 pp. US $28.50.

Of late, iguanas have captured the imagination of the pet buying public. Trade in live iguanas has increased at least tenfold over the last decade and the green iguana (*Iguana iguana*) now ranks behind only the red-eared slider (*Trachemys scripta*) among wild terrestrial vertebrates in international commerce. No wild bird or mammal species is traded in numbers of this magnitude (A. Gaski, pers. comm.). About 90% of the more than 300,000 iguanas marketed each year are destined for the US (Fig. 1). What effect this trade has on wild stocks of iguanas is unknown. Perhaps the demand for iguanas would be lessened if survivorship of the captives was prolonged through knowledgeable caretaking. Frye and Townsend have produced a handbook on care of captive iguanas.

Despite the title, this book will not appeal to biologists. This is a book for pet owners. The first twelve pages describe the biology of wild and captive iguanas. Fifty pages of husbandry suggestions follow, augmented by thirty pages of descriptions of diseases that warrant the attention of a veterinarian. The concluding chapter consists of endearing anecdotes about the junior author's personal menagerie.

There are several valuable features of this handbook. The menu lists will be useful for all iguana owners. The lesson on how to grow sprouts in jars could be new information for some readers. Townsend's anecdotes about the difficulties she has had maintaining strongly territorial animals in her home drives the message home in a singularly effective manner. The layout and binding are pleasant.

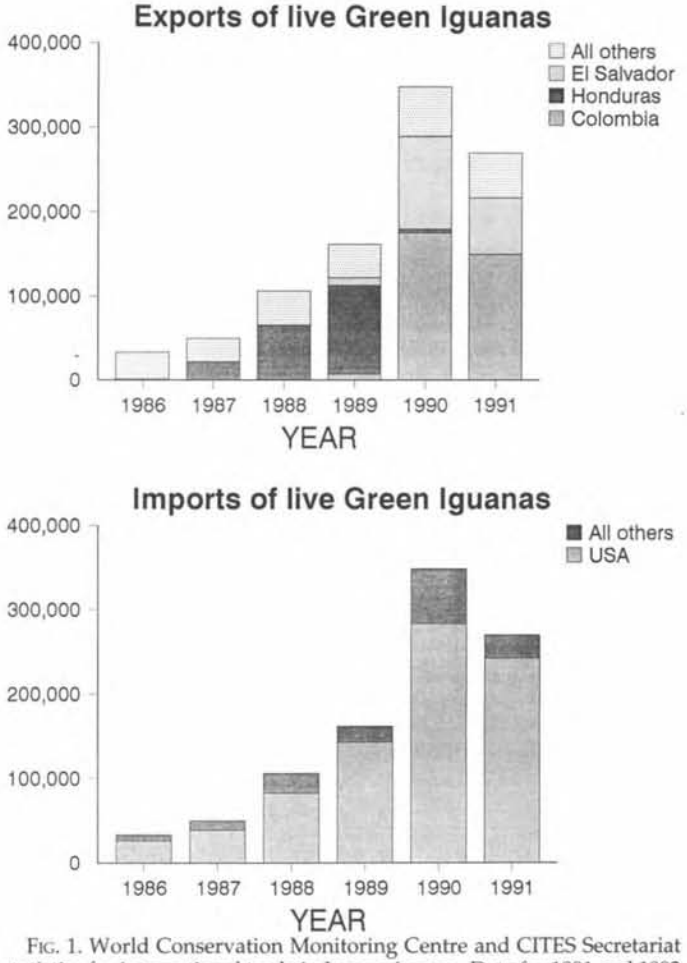

Fig. 1. World Conservation Monitoring Centre and CITES Secretariat statistics for international trade in Iguana iguana. Data for 1991 and 1992 are incomplete at this time, but indicate further increases in exports from Colombia and imports into the US.

Although the book is liberally endowed with Townsend's beautiful if occasionally fanciful drawings of a diversity of iguanines, the focus is narrower. Thirty-four of the thirty-six photographs are of *Iguana iguana*, as is virtually all of the text. For example, the statement, "Six or eight weeks prior to and during courtship, male iguanas acquire bright gold or orange coloring over much of the body, as well as a whitened head," describes only *Iguana iguana* and should be restricted to selected populations of that species (Rodda 1992). The emphasis on green iguanas is appropriate from a conservation standpoint, as few of the other iguanines have wild populations capable of withstanding commercial exploitation (Burghardt and Rand 1982). Unfortunately, concern for this problem is never stated, other than the recognition that several species are "not available in the pet trade."

A potential strength of this book is that the two authors provide very different perspectives. Unfortunately, little was done to integrate their efforts. For example, on at least two occasions virtually identical paragraphs appear within a few pages. The transition between authors is jarring, as the folksy familiarity of Townsend's prose contrasts with the stiff and disjointed jargon of Frye's contributions.

A pet owner is likely to find much of Frye's writing inscrutable. For example, Frye uses a contrasting font to highlight the importance of the obscure phrase "amphigonia retardata," when most readers would be satisfied with calling it sperm storage. Frye doesn't seem to have reached a decision as to his target audience. For example, he gives dosages of a prescription drug for treatment

of herpes, a disease that the pet owner is incapable of diagnosing, but coyly refuses to give information on the appropriate dose of kaopectate to use for iguanas with diarrhea, a readily diagnosable ailment (usually corrected through diet, however).

It appears that neither authors nor editors concerned themselves with the details of manuscript preparation. Within the taxonomic index over half of the scientific names are not italicized, whereas others, even those in the same genus, are. The text refers to Fig. 3 for a view of femoral pores, but these structures do not appear in either Fig. 3 or Fig. 4. I sought help from the index, but information in figures is not indexed. Eventually I stumbled across the pores in Fig. 7. Egg dimensions are captioned as being in cm, but the values given (e.g., 40 x 80) must be in mm. In a throwback to Wynne-Edwards (1962), Frye informs us that "Territoriality . . . serves to preserve each species in its most vigorous state." We are informed that "tall cages must have more than one door . . . Fig. 11," but there is only one door in Fig. 11. Some of the photos (e.g., Figs. 12a, 12b) are pointless, some are too poorly reproduced to detect the item of interest (Fig. 14b), and others are redundant (there are five color photographs to show that regrown tails may be imperfect). Photographs of females mutilated by frustrated territorial males (Figs. 20a, 20b) are labeled as if such mutilation were normal. For a list of toxic plants, the reader is referred to Table 3, which is the list of preferred foods. Some iguanas do well on "toxic" foods (Auffenberg 1982), a consideration omitted from this work.

There is a conspicuous lack of scholarship in the tabulation of data. For example, the table intended to summarize what is known about egg development cites a few anecdotal captive observations for *Iguana iguana*, but neglects a number of significant captive studies (Bagh 1962; Braunwalder 1979 and references therein; Enderlein 1963), including several that are in the recommended readings (Miller 1987; Pütz 1982; Van Aperen 1969). More significantly, the authors completely overlook all data from systematic studies of *Iguana iguana* egg development (e.g., Bock et al. 1989; Licht and Moberly 1965; Müller 1972; Phillips et al. 1990; Rand 1968, 1972; Rand and Dugan 1980; Ricklefs and Cullen 1973; Swanson 1950; Werner 1988; Werner and Miller 1984). One of the table sources, Boylan (1963), does not appear in the literature cited (it is a personal communication cited in another work).

The authors appear insensitive to the unnaturalness of some behaviors seen in captivity. For example, on the basis of captive anecdotes they assure us that iguanas themselves consider homosexual behavior normal. I don't know what opinions iguanas have on the subject, but homosexual mounting is transitory and rare in wild green iguanas (Dugan 1982; Rodda 1992).

I was annoyed by the incessant promotion of business for veterinarians. Frye overly enthuses about the "cadre of well-trained veterinarians" who have an "armamentarium of highly effective" treatments that are available for whatever ails an iguana. The pet owner needs to know when an ailment is serious enough to require professional care, but not all veterinarians are well equipped to deal with exotic pets, and it is arguable that "any unusual lump, or bump, swelling, discoloration, or 'sore' " requires professional veterinary attention. Frye spends most of a page warning readers that untreated flatulence may kill their iguana. He warns that if post-ovipositional females are "depressed" they should be taken to a veterinarian at once. (Post-ovipositional females are probably more in need of a good meal, as they may not have eaten for several months.) He warns readers that "overly large, misshapen, or decomposed eggs with normal shells, infection, or low blood calcium levels are conditions which require immediate veterinary care." I do not know how a pet owner is expected to identify these conditions in the gravid female, nor is any guidance offered.

The book provides a valuable service through the numerous color photographs of iguanas with metabolic bone disease. These photographs will no doubt motivate readers to supply their pet with a nutritional diet. The authors include numerous warnings about the importance of appropriate calcium phosphorus ratios. Unfortunately, they fail to specify what ratio is needed. Their generally useful dietary advice is offset by their inclusion of the grossly erroneous myth that juvenile green iguanas are carnivorous. Although carrion feeding has been observed once in adult green iguanas (Loftin and Tyson 1965), and a single anecdote has been published of a juvenile eating a caterpillar in the wild (Hirth 1963), all other data from wild green iguanas indicates that they are herbivorous at all sizes (Barbour 1932; Iverson 1980, 1982; Rand et al. 1990; Troyer 1982, 1984; Van Devender 1982). Frye and Townsend's Table 2 notwithstanding, insects, arachnids, and eggs are not usual food items for green iguanas. This book makes the controversial declaration that digestive tracts of baby iguanas must be inoculated with unspecified microorganisms, but no information is given as to how this might be accomplished. Elsewhere they specify that coprophagy should be discouraged.

Among the more difficult problems presented to the keeper of pet iguanas is that of reproduction. In my experience, the reproductive cycles of captives are often poorly synchronized, with hormonally excited males attempting to mate or fight with cagemates that are not in breeding condition. This problem is not discussed, nor are any suggestions given for providing the captives with a synchronizing environment. The authors state that females cease feeding 2–3.5 months after copulation. This may be an artifact of reproductive asynchrony; wild iguanas in the llanos of Venezuela cease feeding coincident with copulation (Rodda 1992). Natural reproduction is erroneously characterized in a variety of other ways as well. For example, they state that iguana males mark their females with femoral pore secretions. They may in some areas, but this has not been observed in wild green iguanas (Dugan 1982; Rodda 1992). Contrary to the information given, some iguanines are reported to guard nests (Wiewandt 1982). The authors state that significant embryonic growth does not occur in the several months during which oviducal eggs are retained in iguanas; Licht and Moberly (1965) observed limb buds and a functioning heart at oviposition in *Iguana*. The authors ambiguously state that maturity occurs at age 2 or 3 years depending on whether the iguanas were raised in captivity (which is which?). The available data for wild green iguanas (Zug and Rand 1987) exhibit a mode of five years. The book makes the perhaps ghoulish comment that females "should be healthy and possess excellent flesh" prior to mating. This strikes me like those yellow "child in car" warning labels seen in some cars driven in the U.S. Does this mean a pet owner should not strive to take care of their charges at other times?

While the care recommendations given in this book are generally sound, there are a few that should be refined. For example, there are redundant warnings that pet iguanas may harbor malaria, but the authors fail to note that iguana malarias are not among the malarias that affect humans and are not transmissible to humans. The advice to force feed an iguana if it fails to eat after two weeks must be tempered by the recognition that newly hatched individuals, breeding males, and gravid females normally fail to eat. Newly acquired individuals may need to be maintained in opaque cages for them to begin feeding (Troyer, pers. comm.). There are repeated warnings that cages must be sprayed or animals given water to drink. Pet owners should not become alarmed if their pets fail to drink standing water. Wild green iguanas have been seen to drink only when they are not feeding during the breeding season (Rodda 1992). However, captive iguanas typically suffer from insufficient humidity; spraying the animals and their cages is a useful but often incomplete cure for this problem.

The directions given in this book with regard to humidity are unreasonable. On the one hand they recommend including powerful ventilation fans on cages; on the other they specify 85–95% humidity for tropical iguanas. In my experience, maintaining 85–

95% humidity in cages in typical modern houses is simply impossible even if the ventilation is omitted. Furthermore, if such a high humidity level is attained, mold and pathogens will propagate uncontrollably. The alfalfa pellet substrate that they recommend will rapidly absorb moisture and become unusable in a high humidity environment.

The book's final chapter by Townsend is a delight to read, even if the hijinks reported (e.g., sleeping with "Goober" and "Peanut," smuggling iguanas aboard commercial aircraft in socks pinned to undergarments) provide unfortunate role models. Townsend indicates a willingness to assume that iguanas are capable of assuming human roles: "As [a hatchling] is beginning to get used to the human face, in his eyes, the expression of fear is almost completely replaced by what one might call wonder." Perhaps, but if this leads to animal welfare requirements for daily clean sheets and a mint on their pillow, we will have erred.

Remarkably enough, for a book oozing with affection for iguanas, no effort is made to promote the welfare of wild iguanas. The epilogue vaguely promises that keeping iguanas will somehow help save the rainforest. It will do so only if the display of captives results in effort or at least funds being channeled to rainforest preservation activities. Showing off a pet may simply generate more demand for sales of wild animals. The authors include an appendix listing herpetoculture organizations, but they fail to promote iguana conservation in any meaningful way. Many island iguanines are desperately in need of help. Responsible pet owners will want to support the conservation activities of groups like The Nature Conservancy's International Program or the International Iguana Society. Pet stores and iguana owners should be encouraged to tithe a percentage of their earnings to such efforts.

If you are looking for a book on the biology of iguanas, there is yet no volume to surpass Burghardt and Rand (1982). If you are looking for a book on the pet trade in iguanas, it remains to be written. If you are looking for a guide to care of green iguanas, pick up Beltz (1989) or de Vosjoli (1992). These booklets provide more authoritative information in a more comprehensible form, at a fraction of the price.

Acknowledgments.—J. R. Caldwell (World Conservation Monitoring Centre) and CITES Secretariat provided the data shown in Fig. 1. A. Gaski of TRAFFIC, USA, and W. M. Osborn and R. Tannen of the U.S. Fish and Wildlife Service provided insights into international trade in iguanas. P. Medica supplied valuable references. R. J. Rondeau, T. Fritts, S. Skagen, and A. S. Rand suggested improvements to the manuscript.

GORDON H. RODDA
National Biological Survey
4512 McMurry Ave.
Fort Collins, Colorado 80525, USA.

The Reptiles and Amphibians of South Australia, by Edgar R. Waite. 1929. Introduction by Michael J. Tyler and Mark Hutchinson. Facsimile Reprints in Herpetology, Society for the Study of Amphibians and Reptiles, Oxford, Ohio, USA. 282 pp., color plate, portrait, 192 text figures including numerous photographs. Clothbound. $35.00 US. ISBN: 0-916984-30-3.

This is a handsomely bound facsimile of Waite's classical treatment of the herpetofauna of South Australia. Tyler and Hutchinson have, in characteristic style, clearly and succinctly summarized the importance of Waite's handbook (". . . the first and only complete treatment of the herpetofauna of any Australian state"), painstakingly matched Waite's scientific names with current nomenclature (including footnotes to clarify errors in the original text), and assembled a list of his herpetological publications. Phillip Jones assisted in compiling the Introduction, by locating biographical details from Waite's diaries. The Introduction is beautifully edited, with no typographical errors to my knowledge, and is followed by a faithful reproduction of Waite's entire handbook with original illustrations. The high quality and reasonable price of this truly historical edition, as well as a generally high regard for Australian fauna, should attract the interest of herpetologists and naturalists, alike.

It is both befitting and appropriate that this facsimile volume commemorate the 2nd World Congress of Herpetology, held in Adelaide, South Australia, 29 December 1993 to 6 January 1994. It is befitting because of its parochial significance, and appropriate as a symbol of the ponderously slow pace of herpetological advancement in this vast, but largely unpopulated continent. The fact that Waite's book is still used as a reference is largely due to his many compilations of (sometimes) original observations on natural history of the herpetofauna which, unlike the taxonomy of the group, are largely inviolate. More recent books offer additional natural history notes, as well as outstanding color plates and comprehensive (artificial) keys with current nomenclature. However, close scrutiny of these newer texts reveals that for many groups Waite's observations are repeated and much of the taxonomy consists of identifying a few new species and shifting existing species into and out of different genera, with little or no phylogenetic reconstruction. One formal classification is still as unstable as another, and the present situation for many groups (for example, the elapid snakes) is not much better than in Waite's day. However, phylogenetics is the task of a professional systematist and natural history is often the interest of keen amateur naturalists.

One has to live in South Australia to appreciate the fact that most people in a state larger than Texas are clustered in a few widely scattered cities along the coast. The "outback" is virtually at their doorstep, but few roads allow access to it and many people are reluctant to venture into the place. Moreover, much of the rich reptile life of this vast area is nocturnal or crepuscular, retreating by day to the safety of burrows, rock crevices, deep sand or leaf litter under dry shrubs, to escape the heat and dryness. There are usually only one or two Curators of Herpetology per state, and perhaps that number of professional herpetologists in each of the colleges and universities. Budgets are extremely slim, although there is some support for individuals with clear objectives, innovative ideas, and the patience of Job. Keen amateur herpetologists make up the bulk of the collecting force, but their ranks are effectively thinned by a passion for keeping live specimens (often including venomous snakes and rare pythons), which (in part) contributes to continuous battles with state and federal authorities over collecting permits. Curators and other professionals who intercede on behalf of these collectors are sometimes caught in a vicious triad, and spend a lot of time trying to appease both groups. So, today, the task of revising previous studies is left to a few well-organized and well-positioned workers who, understandably, guard their turf. It must have been simpler in Waite's day, when communications were by occasional letter and visits even less frequent, but with the publication of this book I am reminded that little seems to have changed.

PUBLICATIONS RECEIVED

Ecology of Red Maple Swamps in the Glaciated Northeast: A Community Profile. Francis C. Golet, Aram J.K. Calhoun, William R. DeRagon, Dennis J. Lowry, and Arthur J. Gold. 1993. U.S. Fish and Wildlife Service Biological Report 12, xi + 151 pp. Available at no charge from *Publications Unit, National Biological Survey, 1849 C Street, N.W., Mail Stop 130, Webb Bldg, Washington, D.C. 20240, USA.* Individuals wishing to receive announcements concerning similar scientific publications should send their requests to: *Publications Coordinator, Office of Information Transfer, National Biological Survey, 1201 Oak Ridge Drive, Suite 200, Fort Collins, Colorado 80525, USA.*

This report is part of a series of profiles on the ecology of wetland and deepwater habitats. Red maple swamp is a dominant wetland type in the glaciated northeastern United States, and comprises 60–80% of all inland wetlands in southern New England and northern New Jersey. The information pertaining to amphibians and reptiles is limited to about two pages and briefly summarizes previous ecological studies from the northeastern U.S.

Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986-1993, *et seq.* Privately published by and available from the author (Ralph W. Axtell, 2814 Rock Hill Road, East Alton, Illinois 62024, USA). Individual accounts available separately.

Three newly-published accounts for *Cnemidophorus sexlineatus*, *C. inornatus*, and *C. "laredoensis"* augment twelve accounts issued earlier (see *HR* 24(2):76 for further details). These newest accounts total 56 pages and include an extremely detailed range map for all three taxa.

Ensatina eschscholtzii platensis (Sierra Nevada Ensatina, juvenile). USA: California: Butte Co., Concow Reservoir. Illustration by Tim Manolis.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). ***HR*** especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints.

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes, and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of external reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology.*** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1994

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*

Institutional subscription.....$60.00

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

About the Cover.—The cover illustrations were executed by Jeffrey W. Tamplin, Department of Zoology & Physiology, Louisiana State University, Baton Rouge. Clockwise, from upper left: *Thamnophis exsul* (USNM 166423, holotype: Coahuila); *Thamnophis sumichrasti* (USNM 7079a: Veracruz); *Thamnophis scalaris* (MVZ 144489: Veracruz); *Thamnophis mendax* (LSUMZ 35340: Tamaulipas). Readers interested in the systematics of this group of Mexican garter snakes are referred to the following publication: D. A. Rossman. 1992. Taxonomic status and relationships of the Tamaulipan montane garter snake, *Thamnophis mendax* Walker, 1955. Proc. Louisiana Acad. Sci. 55:1–14.

INSTITUTIONAL PROFILE

Herpetology At The University of Georgia

The University of Georgia is located in the Classic City of Athens, a friendly college town of approximately 90,000 persons (including students) surrounded by a semi-metropolitan to rural area with a population of 160,000. A progressive town with an assortment of interesting restaurants and shops in a pleasant pedestrian-oriented downtown area at the very edge of campus, Athens is recognized world-wide as the Mecca of New Wave music and the downtown is the center of lively clubs, coffee houses, and other entertainment establishments after dark. The city is known for its fine examples of early 19th century antebellum architecture. It boasts two modern hospitals and an assortment of shopping complexes. Bus transportation is readily available throughout the community and on campus. Open rolling hills and forests, with streams and lakes for swimming, canoeing, and fishing are only minutes from town. The University is home to the Georgia Museum of Art and the State Botanical Garden as well as an array of recreation and sports facilities including tennis, golf, racquetball, pools, and intramural fields. Athens is only an hour from Atlanta, host city for the 1996 Olympics, and a major shopping and entertainment center that boasts the fine new Fernbank Museum of Natural History, the Atlanta Zoo, Six Flags, and more. Within a modest drive are the Great Smoky Mountains, the Okefenokee Swamp, and Georgia's Golden Isles, the barrier islands.

Piedmont oak-pine forest

History of Herpetology at the University of Georgia

The University of Georgia is the nation's oldest Land Grant institution, incorporated in 1785. The first modern natural historian associated with the University of Georgia was Eugene Odum, the father of modern ecology. Although Gene's early work focused primarily on birds and mammals, and later, of course, on ecology, several of his students, notably John Crenshaw and Robert Gordon, specialized in herps. Herpetology began in earnest with the arrival of Bernard Martof in the early 1950's. Martof was most noted for his work on salamanders and frogs and his 1956 *Guide to the Reptiles and Amphibians of Georgia*. Martof, along with Don Scott and their students, such as Robert Humphries, were active in developing the significant herpetological collections now associated with the Museum of Natural History. With the arrival of Whit Gibbons at the Savannah River Ecology Laboratory, a unit of the University of Georgia located at the Savannah River Site near Aiken, South Carolina, in 1967, and later Justin Congdon, the Savannah River Ecology Laboratory and the University of Georgia became an acknowledged

PIT-tagging a common kingsnake at SREL

center of herpetological research. Throughout the past 15 years the Savannah River Ecology Laboratory has been recognized for its research in population dynamics and ecology of reptiles and amphibians. Numerous students and postdoctoral research associates who have gone on to careers in herpetology include Harold W. Avery, Miriam Benabib, Laura A. Brandt, Janalee P. Caldwell, David B. Clarke, James O. Farlow, Bruce W. Grant, Trip Lamb, Jeff Lovich, Mary T. Mendonca, Stephen J. Morreale, David H. Nelson, Robert R. Parmenter, Richard A. Seigel, Raymond D. Semlitsch, Edward A. Standora, Anton D. Tucker, and Laurie J. Vitt.

Facilities

The University of Georgia boasts a number of facilities and resources attractive to students and researchers with interests in herpetology. The Savannah River Ecology Laboratory is a permanent research facility with resident faculty of the University of Georgia. Herpetological research facilities include experimental ponds, terrestrial enclosures, holding tanks, electrophoretic and molecular genetics laboratories, reptile and amphibian animal

care facilities, and approximately 300 square miles of protected field sites.

The Institute of Ecology is a multidisciplinary research unit with modern laboratory and computer facilities housed in the Ecology Building on campus. Other significant facilities include the Marine Institute on Sapelo Island, Skidaway Institute of Oceanography, Coweeta Forestry Experiment Station in North Carolina, and the Horseshoe Bend Research Site in Athens. The University is an active participant in the Organization of Tropical Studies in Costa Rica and Highlands Biological Station in Highlands, North Carolina. The University of Georgia Museum of Natural History is a major repository maintaining extensive research collections in numerous areas including approximately 25,000 herps from Georgia and the Southeast. Specific requests for information are welcome at any time. Admission to the collection is by appointment only; attendees of the SSAR/HL 1994 meeting wishing to visit the collection must schedule a time in advance. For more information please contact the Collections Manager, Elizabeth McGhee (tel. 706-542-3940). A listing of the Museum's herpetology holdings can be found on the University of Georgia's Gopher computer, which can be used by any computer that has Internet access (gopher.uga.edu). The University of Georgia Library, with more than 3 million books, is one of the largest in the nation, and subscribes to 96% of all biological and chemical publications covered in *Current Contents*. On-line computer services provide the capacity to search over 500 data bases from any computer on campus. Other University facilities include a CDC Cyberplus 960 and IBM mainframe 3090, Center for Advanced Ultrastructural Research, Molecular Genetics Instrumentation Facility, and Biological Sequence/Structure Computation Facility, among others.

Experimental ponds at SREL

Academic Programs

The Biological Sciences are particularly well represented at the University of Georgia. Departments offering undergraduate and advanced degrees include Biochemistry, Botany, Entomology, Genetics, Microbiology, and Zoology, as well as the School of Ecology and the School of Forest Resources. The majority of students and faculty with an interest in herpetology have been associated with either the Department of Zoology, the Institute of Ecology, or the Savannah River Ecology Laboratory. Traditionally, academic degrees have been awarded through Zoology (M.S. and Ph.D.) or the Graduate Program in Ecology (Ph.D.). As a result of recent recognition of the Institute of Ecology as the School of Ecology and its reorganization as an academic unit, most of the ecological, organismal, and systematics teaching and research programs associated with the former Department of Zoology have now been transferred to the School of Ecology. Researchers and students here have broad interests in population and community ecology, conservation biology, marine, freshwater and thermal ecology, tropical and temperate forest ecology, as well as traditional areas of organismal and systematic biology.

Rushing stream at Highlands Biological Station.

University Faculty Research Programs

John Avise (Professor, Department of Genetics)—John's interests include the evolutionary genetics and ecology of natural populations, especially the processes governing the distribution of genetic variability within and among species. His approach is largely empirical and utilizes information obtained from morphology, protein variation, and especially mitochondrial DNA heterogeneity. His research topics range from microevolutionary problems of population structure analysis to macroevolutionary concerns relating to speciation and phylogenetic reconstruction. While John's work encompasses a variety of vertebrate and invertebrate groups, many of his papers have focused on amphibians and reptiles.

Brian R. Chapman (Assistant Professor, School of Forest Resources)—Most of Brian's recent research has focused on the ecology of both birds and mammals, but he has also conducted status surveys for threatened and endangered amphibians in several states. He has several current projects involving the effects of forest management practices on reptiles and amphibians in Georgia.

Justin Congdon (Senior Research Ecologist, SREL)—Justin's interests are in the broad area of evolutionary ecology. His research focuses on physiological and bioenergetic processes

Eastern glass lizard and eggs.

that shape life history traits and, in addition, on the population biology of long-lived organisms.

Nat B. Frazer (Associate Director, SREL)—Nat's early research focused on the ecology and demography of loggerhead turtles and eventually moved to modeling life history patterns of other sea turtles. At SREL he has been primarily involved in the demography and basic ecology of freshwater turtles, including the preparation of life tables using long-term data bases.

J. Whitfield Gibbons (Professor of Ecology, SREL)—Whit's research interests center around studies on life history, demography, and ecology of reptiles and amphibians, especially freshwater turtles; these include studies on longevity and aging phenomena in reptiles, patterns of herpetofaunal biodiversity, and responses of herpetofauna to stress phenomena associated with energy technologies and industrial activities.

Chester Karwoski (Professor, Department of Psychology)—Chet specializes in cellular physiology in amphibians and reptiles in response to environmental stimuli. His work encompasses circadian rhythm in *Anolis carolinensis* in response to light, retinal cell physiology of *Rana*, and intercellular physiological studies in *Necturus*.

Joshua Laerm (Director, Museum of Natural History)—Although most of Josh's recent work has been with mammals he retains an interest in herps and is presently involved in broad ranging surveys of amphibians in the mountain provinces of Georgia.

Jim Richardson (Adjunct Research Professor, Institute of Ecology)—Jim is widely recognized for his work on marine turtles. His particular research interests are in population ecology and management of turtle populations both regionally and worldwide. Jim has developed long term data bases from nesting records at a number of sites which are critical for long term population monitoring and conservation.

Robert J. Warren (Professor, School of Forest Resources)—Although Bob is widely recognized for his research on deer physiology and reproduction, wildlife contraception, and the effects of predator reintroductions, he is also involved in studies of the impacts of predators and scavengers on the reproductive success of endangered sea turtles.

Graduate Student Research Programs

The research activities of numerous graduate students at the University of Georgia and SREL focus on herpetological questions, including projects by Kathleen Barker (distribution and habitat preferences of montane salamanders in NE Georgia), Kurt Buhlmann (population ecology and conservation genetics of turtles), Vincent Burke (terrestrial activities of freshwater turtles), Robert Fischer (behavior, morphology, and physiology of reptiles), Frank Hensley (energetics of tadpoles), Chris Hudson (genetics and ecology of amphibians), Mark Komoroski (amphibian egg lipid energetics in relation to life history), John Krenz (population genetics and ecology of salamanders), John Lee (winter behavior and ecology of cottonmouths), Mark Mills (ecology of reptiles and amphibians in response to natural and human-caused fires), Joe Pechmann (aquatic and terrestrial density-dependence and long term population dynamics in amphibians), Mary Ratnaswamy (raccoon ecology and depredation of loggerhead and green sea turtle nests), David Scott (life history, demographics, and ecology of salamanders), DeEtte Walker (geographic variation in the mud turtle), Mark Wilson (amphibian retinas), Brian Wunschl (amphibian retinas), Rebecca Yeomans (orientation and homing ability of turtles), Huaiyuan Yu (amphibian retinas).

SSAR/HL Meeting Highlights

Dates: 27 July–1 August 1994
Place: The University of Georgia, Athens, Georgia

Keynote Lecture: "The Evolution of Reptilian Viviparity Revisited," by Richard Shine (University of Sydney).

Forum: "Issues in Conservation: Point-Counterpoint." *Moderator*: Robert Jaeger. *Speakers*: Henry Wilbur and S. Bradley Shaffer.

Symposium: "Field and Behavioral Endocrinology." *Organizer*: Diana Hews. *Participants:* Dale DeNardo, Kent Dunlap, Tyrone Hayes, Lynne D. Houck, Rosemary Knapp, Catherine A. Marler, Robert T. Mason, Mary Mendonça, Catherine Propper, Matthew Rand, and Thane Wibbels.

Symposium: "Interfaces Among Inter-individual Variation, Life Histories, and Population Dynamics of Reptiles and Amphibians." *Organizer:* Arthur E. Dunham. *Participants not yet finalized.*

Symposium: "West Indian Herpetology: A Symposium in Memory of Albert Schwartz." *Organizers:* Robert W. Henderson and Robert Powell. *Participants (tentative)*: Karen Anderson, Karen A. Bjorndal, Alan B. Bolten, Hans E. A. Boos, Ellen J. Censky, Brian I. Crother, Mark L. Day, C. Kenneth Dodd, Jr., Karen L. Eckert, Alberto R. Estrada, Richard Franz, Mary Garvin, Carla A. Hass, S. Blair Hedges, Duncan Irschick, Thomas A. Jenssen, Hinrich Kaiser, James D. Lazell, Julian C. Lee, Allen R. Lewis, Jonathan B. Losos, Walter E. Meshaka, Jr., José A. Ottenwalder, Octavio Pérez-Beato, G. Larry Powell, Douglas P. Reagan, Jonathan Roughgarden, Anthony P. Russell, Andreas Schubert, Sharoni Shafir, Margaret M. Stewart, Richard Thomas, Roger S. Thorpe, Peter J. Tolson, Daniel S. Townsend, and Peter Vogel.

Colloquium: "Turtle Biogeography and Phylogeography." *Organizer:* Brian Bowen. *Participants:* Eugene S. Gaffney, S. Bradley Shaffer, Scott Davis, Edward O. Moll, Fredric J. Janzen, DeEtte Walker, Sandra Encalada, Peter Dutton, and Anna Bass.

Herpetological Travelogue Slide Shows: Profusely-illustrated lectures of exotic herps and their habitats.

Multimedia Presentations: "Herps of the West," and "Amphibians of the Appalachians," by David Dennis and Eric Juterbock; "Namesakes of North American Amphibians and Reptiles" (new) by Kraig Adler and David Dennis.

Oral and Poster Sessions: Several concurrent sessions each day.

Student Paper Awards: Seibert Prizes (SSAR) to be awarded to the two best student-presented papers at the meeting ($250 first prize, $150 second prize). The Herpetologists' League Award for Graduate Research is for the best student-authored manuscript; winner receives $500 and ten years back issues of *Herpetologica*.

"The Great Reprint Scavenge" (for students only!). Professionals are asked to clear unwanted duplicate reprints out of their offices (and receive free raffle tickets as a "thank you").

Social Activities: Welcoming Social, the SSAR Annual Auction, Barbecue Picnic, Graduate Student Program ("Graduate School: The Greatest Pit-fall Trap of All") & Social, local tours.

Field Trips: Zoo Atlanta, Savannah River Ecology Lab, Highlands Biological Station, Okefenokee Swamp, and Sapelo Island.

Art Exhibit: Featuring art with a herptile focus. $100 cash award for the art work judged unique and interesting.

Live Exhibit: Featuring herps of the region. Sponsored by Savannah River Ecology Lab.

Costs: Registration $80 student, $115 regular; $160 late registration fee after 20 June. Lodging at Residence Hall (air-conditioned dorms): $13 person/day (double occupancy) and $19 person/day (single occupancy). Lodging at Georgia Center (meeting location) or local Hotel: $45-$51/day (single occupancy) and $52-$55/day (double occupancy).

Further Details: See December 1993 issue of *Herpetological Review* (pages 117–119). Meeting Announcement/Call for Papers will be mailed to all North American members of SSAR and HL in March 1994, or on request from *Amy Edwards, Program Coordinator, Museum of Natural History, University of Georgia, Athens, Georgia 30602, USA (telephone 706-542-4137; FAX 706-542-3920; email AEDWARDS@ZOOKEEPER.ZOO.UGA.EDU).*

SSAR BUSINESS

SSAR Election Results

Results of the recent SSAR election are as follows:

President-elect (to serve as President for 1995): Alan H. Savitzky.

Secretary: J. Eric Juterbock (unopposed).

Treasurer: Karen L. Toepfer (unopposed).

Directors: Janalee P. Caldwell, Paul E. Moler.

Donations Needed For SSAR Symposium

"West Indian Herpetology: A Symposium in Memory of Albert Schwartz," is to be held at the 1994 SSAR/HL meeting. Several of the invited participants living in the West Indies require assistance with travel expenses in order to attend the symposium. Donations are being sought from individuals and institutions to help defray travel costs.

All donations are tax-deductible, and may be made payable to "SSAR–Albert Schwartz Symposium," and mailed to *Dr. Robert Powell, Department of Natural Sciences, Avila College, 11901 Wornall Road, Kansas City, Missouri 64145, USA (tel. 816-942-8400 ext. 2352; fax 816-942-3362).* All contributors will be acknowledged in the symposium program and in any publications emanating from the symposium.

SSAR Symposium Organizers

Individuals organizing symposia for the 1995 or 1996 annual meeting should contact the SSAR Meeting Events Coordinator for guidelines. Please send inquiries to: *Don C. Forester, Biological Sciences, Towson State University, Towson, Maryland 21204, USA. e-mail: In%"E7BFOR@toe.towson.edu", Tel. (410) 830-2385, Fax (410) 830-2604.*

"HERPETOLOGY OF CHINA" *Date of Publication*

Because knowledge of the precise date of publication is important for taxonomic works, we wish to record that our book, "Herpetology of China," was issued on 29 November 1993. Due to unforeseen delays in printing and binding, publication was delayed one month from the date printed in the book.

A NEW JOURNAL

Russian Journal of Herpetology

(in English)

Russian Journal of Herpetology is an international, multidisciplinary journal and publishes articles covering both basic and applied research on recent and fossil amphibians and reptiles. All aspects of herpetology including systematics, distribution, speciation, phylogeny, morphology as well as behaviour, ecology, and toxinology of amphibians and reptiles will be presented.

Of particular emphasis is the conservation of species of amphibians and reptiles, their associations and habitats. Although much attention is given to fundamental research, papers devoted to breeding in captivity and propagation of amphibians and reptiles will be welcomed and presented in the special part of the journal.

The ultimate aim of the journal is to provide an effective medium for communication of the latest and best scientific information from the expanding, interdisciplinary, and international scientific community focusing on new methods and ideas in progress and to promote cooperation between Russian and foreign scientific and commercial organizations.

Types of Contributions

- original papers
- invited or contributed reviews on specific topics
- short communications on topics of immediate interest, new methods and ideas in progress
- notices of meetings, symposia and short courses
- book reviews

NEWSNOTES

Southwestern Research Station Volunteer Program

Approximately 20 volunteer positions are open in 1994 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for 24 hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between 15 March and 1 November. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by 15 February, summer volunteers (June–August) by 1 April, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA; Tel. (602) 558-2396.*

New Publication

Dumerilia is a new herpetological series published by the Association des Amis du Laboratoire des Reptiles et Amphibiens du Muséum, Paris (AALRAM). The first volume, "Liste bibliographie des Reptiles actuels. I. Chéloniens" (128 pp. by Patrick David) will appear by the end of 1993. Subsequent volumes will cover all reptiles. Each volume in this series of checklists contains: 1) a list of all taxa (species and subspecies) currently recognized as valid within the group covered, by scientific name (with author and date) and English and French common names; 2) a list of selected references for each taxon to direct the reader to the major references; 3) a bibliography for all publications mentioned and a full citation for each publication.

The turtle volume may be purchased for $26 (individuals) and $52 (institutions) from the *AALRAM c/o Patricia B. Zug, Division of Amphibians & Reptiles/mrc 162, National Museum of Natural History, Washington, DC 20560.* Please make checks payable to ALLRAM. Subsequent volumes of *Dumerilia* will be offered at a discounted prepublication price.

Vial Retires As DAPTF Coordinator

Dr. James L. Vial, IUCN/SSC Declining Amphibian Populations Task Force Coordinator since its inception in 1991, has announced his retirement effective 31 December 1993. From a start-up working group of 12 persons, the Task Force now numbers over 1200 collaborators in 91 countries or regions.

The herpetological community is indebted to Jim Vial for his efforts in developing the DAPTF program and helping to establish numerous working groups. Persons interested in obtaining additional information about the DAPTF or its newsletter, *Froglog*, should contact: *Coordinator, DAPTF, EPA Environmental Research Laboratory, 200 SW 35th Street, Corvallis, Oregon 97333, USA. Tel. (503) 754-4798.*

New Turtle Journal

The inaugural issue of *Chelonian Conservation and Biology*, the new scientific Journal of the IUCN/SSC Tortoise and Freshwater Turtle Specialist Group and International Bulletin of Chelonian Research, was published in November, 1993. The journal is published by Chelonian Research Foundation with support from Conservation International, Chelonia Institute, NYZS/The Wildlife Conservation Society, Florida Audubon Society, and IUCN (The World Conservation Union) - Species Survival Commission. The journal is co-edited by John L. Behler, Peter C.H. Pritchard, and Anders G.J. Rhodin, with the Editorial Review Board comprising several well-known turtle biologists and conservationists: Indraneil Das, C. Kenneth Dodd, Jr., Arthur Georges, J. Whitfield Gibbons, John B. Iverson, Michael W. Klemens, Jeffrey E. Lovich, Russell A. Mittermeier, Edward O. Moll, David J. Morafka, Ian R. Swingland, Bern W. Tryon, and George R. Zug.

Manuscripts are welcome from any individuals, and are not limited to members of the Specialist Group. Manuscripts may cover any aspects of turtle and tortoise research with an emphasis on conservation or biology. Studies on freshwater turtles and tortoises are of primary interest, but articles on marine turtles are also welcome. Manuscripts dealing with conservation biology, systematic relationships, chelonian diversity, geographic distribution, natural history, ecology, reproduction, morphology and natural variation, population status, and human exploitation or conservation management issues are of special interest. Either full-length original research articles or shorter notes and field reports are welcome. English translations of foreign language articles are potentially of interest. Newsnotes and announcements of interest to the turtle conservation and research community are also welcome. All manuscripts will be submitted for review by the Editorial Staff and selected members of the Editorial Review Board, as well as independent outside peer-review as necessary. Manuscripts should be submitted in triplicate to A.G.J. Rhodin at the address below, preferably accompanied by a computer disk in either Macintosh or IBM format.

Subscription rates are for a full volume of four published issues, with two issues planned per year. Subscription rates are US$ 25 for individuals and US$ 50 for institutions, with a US$ 20 surcharge for Air Mail to foreign addresses. Make checks or money orders payable to Chelonian Research Foundation and remit to: *Anders G.J. Rhodin, Chelonian Research Foundation, 168 Goodrich Street, Lunenburg, Massachusetts 01462, USA.*

Gopher Tortoise Council Research Award

In honor of his numerous contributions to the biology of the gopher tortoise and its sandhill community, the Gopher Tortoise Council has named its student research award the J. Larry Landers Student Research Award. Those wishing to contribute to the fund should send their contributions to Brian Bearwood, Treasurer, Gopher Tortoise Council, P.O. Box 13, Mariana, Florida 32447, USA.

The J. Larry Landers Student Research Award is presented annually to the best student research project concerning the biology of the gopher tortoise, *Gopherus polyphemus*, or any aspects of its sandhill community. Recent awards have averaged $400. Deadline for receipt of proposals to be considered for the 1994 award is 31 August 1994. Students interested in applying should submit a concise description of their project with a detailed budget and a brief curriculum vita to: *Bob Herrington, Research Advisory Committee, Department of Biology, Georgia Southwestern College, Americus, Georgia 31709, USA.*

Summer Course In Larval Amphibian Biology

The Highlands Biological Station, located in the Blue Ridge Mountains of southwestern North Carolina, is offering a course in Larval Amphibian Biology, to be taught by Dr. Richard J. Wassersug of Dalhousie University and guest instructors. This is a lecture, laboratory, and field course addressing a variety of topics on the biology of amphibian larvae. Among the topics to be covered are: the identification of local larvae, the evolution of complex life cycles and metamorphosis, and the feeding behavior of tadpoles and salamander larvae. Assorted aspects of the morphology, ecology, behavior, and population genetics of amphibian larvae that reflect the special interests and expertise of the instructors will be emphasized. Students will conduct individual projects of their own design and execution. Course dates are 6–17 June 1994.

The course is designed for advanced undergraduate and graduate students. Course credit is available from either Western Carolina University or the University of North Carolina at Chapel Hill. For further information and application form contact: *Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA. Tel. (704) 526-2602.*

Summer Course In Tropical Diversity

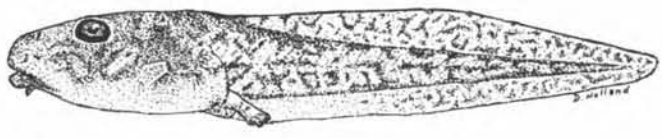
The Organization for Tropical Studies (OTS) will be offering *Tropical Diversity and Conservation* in Costa Rica, 1–23 August 1994. This course is designed to be an intensive, field-oriented introduction to tropical diversity in rainforest, seasonally dry forest, and cloud forest ecosystems. The program consists of orientation walks, faculty-led field research projects, discussions, and lectures. The course will be held in Costa Rica at the OTS-operated field stations in lowland rainforest (La Selva) and seasonally dry forest (Palo Verde), and at a mid-elevation site, Volcán Cacao, in Guanacaste National Park. After one day of orientation and introductory lectures in San José, the class will operate entirely in the field spending one week at each site. The coordinator is Dr. Maureen Donnelly, University of Miami. Enrollment is limited to 22 persons. Past participants have ranged from advanced undergraduates to established biology faculty seeking an introduction to tropical biology. The application deadline is 15 April 1994, with selection announcements to be made by 15 May 1994. For further information, including costs and other admission criteria, or to apply, contact: *Organization for Tropical Studies, Box 90630, Durham, North Carolina 27708-0630, USA. Tel. (919) 684-5774, Fax (919) 684-5661.*

MEETINGS

Aquatic Fauna In Peril: The Southeastern Perspective

The Tennessee Aquarium is sponsoring a conference to be held 31 March–1 April 1994 in Chattanooga, Tennessee. The purpose of this two-day meeting is to focus on the problems facing the imperiled aquatic fauna of the southeastern United States. It will provide a thorough historical review of the imperiled aquatic animals of the Southeast as well as a review of the management efforts aimed at conserving and restoring these faunas. Presentations will also address the management of aquatic ecosystems in the Southeast, the roles of government and the public in aquatic conservation, and the formulation of a unified practice of resource management. Sessions are scheduled that specifically address imperiled amphibians and reptiles and their management. For further information contact: *Tennessee Aquarium, Attn. Janet Allen, P.O. Box 11048, Chattanooga, Tennessee 37401, USA. Tel. (800) 262–0695; FAX (615) 267–3561.*

17th Annual AFHC



The All Florida Herpetology Conference will be held 9 April 1994 at the University of Florida in Gainesville. The Florida Museum of Natural History and Gainesville Herpetological Society are co-sponsors. Morning talks are devoted to conservation and natural history, with afternoon talks concerning captive breeding of amphibians and reptiles. Two disease prevention workshops, as well as a young herpetologists' workshop, wil be held concurrently. "Maintaining Collection Security" will be the topic of the late afternoon talks and panel discussion. An evening barbecue will be held at the museum. To pre-register, call or write to *Dr. David L. Auth, Division of Herpetology, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA. Tel. (904) 392-1721.*

Wildlife Water Development Symposium

The Water for Wildlife Foundation is sponsoring the second Wildlife Water Development Symposium to be held at the University of Wyoming, 27–29 April 1994. The primary focus of the workshop will be to provide a forum for discussion and presentation of work and ideas regarding the state of the art of wildlife water developments. Topics to be covered in the workshop will include: Recent Developments in the Field of Wildlife Water Development; Developing Low Maintenance Water for Wildlife; Developing Wetlands and Riparian Areas to Provide Water to Wildlife; Management of Water Developments for Wildlife; Maximizing Multiple Use Options; Optimizing Habitat Values in Association with Water Developments; Utilizing Produced Water from Industry and Agriculture for Water Developments for Wildlife. For further information contact: *Susan Powell, School of Extended Studies & Public Service, University of Wyoming, P.O. Box 3972, Laramie, Wyoming 82071-3972, USA. Tel. (800) 448–7801.*

Herpetology Weekend

The U.S. Forest Service, Kentucky State Parks, and Kentucky Department of Fish & Wildlife Resources are sponsoring a Herpetology Weekend, 8–10 April 1994 at Natural Bridge State Park in Slade, Kentucky. Presentations will be made by Jim Harrison (Miami Valley Serpentarium), Dave Dennis (Ohio State University), and Sherman Minton (Indiana University). Activities will include field trips, night hikes, photo opportunities, and a tour of the Miami Valley Serpentarium. Programs start at 8:00 p.m. on Friday, 8 April at the Activities Center at Natural Bridge State Resort Park. For additional information contact: *Natural Bridge State Park, tel. (606) 663-2214 or (800) 325-1710, or the Stanton Ranger District, tel. (606) 663-2852.*

IN MEMORIAM

Howard Kirke Swann (1919–1993) Bookseller Extraordinaire

Wheldon and Wesley Ltd., the largest dealer specializing in natural history books, celebrated its 150th anniversary in 1990. The company has had a longstanding and well-deserved reputation for integrity and service to an international clientele, a stature that was personified by the company's chairman, H. K. Swann, who died at the age of 74 on 27 October 1993. Howard was known to several generations of herpetologists throughout the world for his careful attention to their library-building needs and he was a generous host to those who visited Wheldon and Wesley's establishment, which since 1957 has been located in the rolling English countryside north of London, almost halfway to Cambridge. Besides bookselling, Howard was involved in book publishing, including reprints of scarce classical works such as Boulenger's British Museum catalogues, the herpetological volume in Anderson's "Zoology of Egypt" series, and Jan and Sordelli's great atlas of snake illustrations. Howard was also the editor for the revised edition of Pitman's "Snakes of Uganda," which was published by Wheldon and Wesley in 1974.

Howard had a boyhood interest in natural history, particularly birds, and although he qualified for entry at Oxford to read classics, he soon entered the army, was captured by German troops shortly before Dunkirk, and spent five years as a prisoner of war. The latter gave him the opportunity to learn German well; indeed, he had a particular facility with foreign languages, including Japanese which he decided to learn quite late in life. After the war, together with his older brother, C. K. Swann, he joined Wheldon and Wesley, a firm that their father had entered in 1904. Howard's amateur interest in natural history was a convenient entrée to the company's line of business and he maintained that interest throughout his life. Among other posts, he held offices in the Hawk and Owl Trust and the Society for the History of Natural History.

Howard's knowledge of books and authors was encyclopedic. Searching through the company's storerooms I often found interesting but incomplete fragments of books—often just a few pages or plates—for which Howard invariably knew all the details about author and title at a moment's glance (and which I could then check later against complete copies). On other occasions I appealed to Howard for help in completing the new introductions to volumes in the SSAR *Facsimile Reprints in Herpetology* series or for biographies in the book "Contributions to the History of Herpetology." Sometimes this involved obscure bibliographic details that are simply unavailable in any existing reference books. Howard's replies were always prompt (he relished the challenge) and often were accompanied by relevant original material that he ferreted out of the enormous accumulated stocks at Wheldon and Wesley's. This scholarly interest in the business is unusual in booksellers today and, together with his friendly nature, will be greatly missed by me and the many others who were privileged to know him.

ARTICLES

Body Color Polymorphism In The Snake *Trimeresurus flavoviridis* On Okinawa Island, Japan

Some snake species show intrapopulation variation in pattern type or body color, but there are few studies that describe color frequencies (Camin and Ehrlich 1958; King 1987) or that analyze the mechanisms of color determination (Zweifel 1981). On Okinawa Island, the habu, *Trimeresurus flavoviridis* (Viperidae), exhibits a polymorphism in dorsal body color (Takara 1962). Most have a yellow ground color, although a few are white. In this paper we quantify the frequencies of the two morphs in mother/offspring groups and present evidence on the mechanism of color determination.

Two-hundred forty hatchlings and 67 full-term embryos were obtained from eggs laid by 55 females collected on Okinawa Island from 1981 to 1992. The eggs of most hatchlings were incubated at a fluctuating temperature in individual containers. The snakes were classified as yellow or white, with the exception of three adults that were intermediate in color.

Yellow individuals were most common: 49 of 55 adults (89%) were yellow, three adults (5.5%) were intermediate, and three adults (5.5%) were white. We obtained no clutches containing only white offspring. Five clutches included both white and yellow young; 49 clutches included only yellow progeny; and the single yellow offspring of a white female could have represented either condition (and is excluded from further consideration). There appeared to be an association between maternal and offspring color: 47 of 49 clutches (96%) of yellow mothers were all yellow, as were 2 of 3 clutches (67%) of intermediate mothers, and 0 of 2 clutches of white mothers. The other five clutches included both white and yellow offspring, with approximately equal numbers of each color in each clutch (Table 1).

TABLE 1. Composition of clutches containing both white and yellow offspring.

Maternal color	Clutch size*	Number of Individuals	
		Yellow	White
Yellow	7	4	3
Yellow	5	2	3
Intermediate	9	4	5
White	9	3	6
White	5**	2	2
Total	35	15	19

* Number of fertilized eggs.
** One embryo died early in development.

TABLE 2. Observed and expected color frequencies in the progeny under two hypotheses of genotypic color determination.

Condition	Frequency	Observed (%)	Hypothesized Dominant	
			White Expected (%)	Yellow Expected (%)
Yellow mother: mixed clutches/ all clutches	2/49	4.1	5.8	17.9**
white hatchlings/ all hatchlings in mixed clutches	6/12	50.0	50.7	28.4*
White mother: mixed clutches/ all clutches	2/2	100.0	100.0	42.8*
white hatchlings/ all hatchlings in mixed clutches	8/13	61.5	54.0	56.8

* $P = 0.1$;
** $P < 0.05$ (Fisher's exact test); other expected frequencies were not significantly different from the observed ($P > 0.1$).

The frequency of white individuals in the maternal generation was 5.8% (excluding intermediates from the sample). If body color is determined genotypically at a single locus, and the white allele is dominant, the white allele frequency in the maternal sample would have been about 2.9% (half the alleles in the white mothers). If body color is genotypically determined at a single locus, but the white allele is recessive, the frequency of the white allele would have been about 24% (all alleles in white specimens and half of the alleles in presumed heterozygotes). The observed color frequencies in the progeny closely conform to the values expected under the dominant white allele model (Table 2). Thus, ground color in *T. flavoviridis* in Okinawa may be determined by a single locus, with a relatively rare (about 3%) dominant white allele.

Acknowledgments.—We thank many persons for collecting gravid females, Akira Nakachi for help with the literature, Hitoshi Shiroma for comments on a draft, and Gordon Rodda and Richard A. Seigel for improving the manuscript.

POINTS OF VIEW

Iguanians And The Cladistic Party Line

Frost and Etheridge (1993) have mistaken what is "the most controversial aspect of cladistics," or at least the most important difference between cladistics and evolutionary systematics. That aspect or difference is in how we perceive and understand relationship. For Hennig (1950), relationship was absolutely and unequivocally nothing more than the inverse of relative lineage age: time, and time alone, distances relationship. Thus, if one can construct a dendrogram of the temporal sequence of lineage branching events, that would—for Hennig and the cladists—be a precise picture of relationship. Hennig's "relationship" is a property of organismal lineages precisely equal to the inverse of lineage age.

For the evolutionary systematist, relationship is ever-so-much more complex. We hope for a system that codifies evolution, and we immediately see that evolutionary rates and roles are enormously variable in time. I would go so far as to say that no two lineages evolve at the same rate during any given period of time, and that no single lineage evolves at the same rate during all of its earthly tenure.

Thus, while an accurate dendrogram of the temporal sequence of branching events would be a very useful component of relationship assessment, it could never—for the evolutionary systematist—be the whole picture.

The origin of higher taxa is a problem for all systematists. All valid genera, for example, must originate as single species. During their tenure in monotypy, then, novel genera do enjoy the same objective reality as other biological species. As soon as a genus becomes polytypic, however, it becomes an abstraction: a word, not a thing.

The cladistic form of taxon definition, "*Novogenus* consists of *N. primus* and all of its descendents," confronts all systematists (not just cladists) with the uncomfortable fact that *Novogenus primus* was, in very real and meaningful ways, more closely related to its immediate ancestors in *Oldogenus*, and probably some other species in *Oldogenus*, than it is or will be to some of its descendents. The cladistic solution is to elevate every member of *Oldogenus* to the rank of an independent, new genus at the instant any one of them becomes differentiated enough to merit such status.

How does this inform us of relationships? How is the relationship of species A to species B altered by evolutionary events—no matter how major—in independent lineage C?

Cladistic methodology is no more objective than that of qualified, educated, evolutionary systematists. The cladist selects characters subjectively, decrees their polarity subjectively, and subjectively assigns them weight or value (most irrationally when all are decreed precisely equal).

Frost and Etheridge (1993) state that "leading systematists" cleave to the cladistic party line. Maybe so, but that begs many questions: leading in what sense? Number of new names coined for old taxa? Number of pages published divided by number of new facts presented (ah, but division by zero is impossible). Whom do they lead? Where do the followers get led to in terms of understanding evolution?

I love cladograms. I think they are sometimes a great help in trying to understand relationships. I often, however, suspect they are far more invented than "recovered." I note that different sets of characters almost invariably produce different cladograms (because different sorts of characters evolve at different rates within and between lineages, of course). I acknowledge that,

given X different cladograms for a group, X-1 of them *Have to be wrong*. I question that making consensus cladograms out of X-1 certainly wrong trees and maybe one right one has much to do with science or reality. . . .

What has all this to do with the Iguania? Practically nothing. Frost and Etheridge did not produce an unequivocal, compelling iguanian cladogram. The characters they used were mostly just modal differences or features demonstrably plastic and variable. Even if the groups they proposed really were based on a correct understanding of the temporal sequence of events, that would not necessitate giving them formal nomenclatural status as families.

Chaos has been generated and, sadly, will long reign.

In Response To Bringsøe On The Inclusion Of *Dendrobates* And *Phyllobates* In Appendix II Of CITES

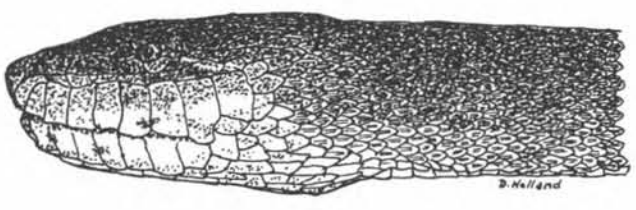
Bringsøe (1992) described what he viewed as the total lack of logic behind adopting all members of the genera *Dendrobates* and *Phyllobates* into CITES Appendix II. He argued that this is "unjustified" and it "impugns the reputation of the Convention." He continued to state that the only possible course of action to correct this embarrassing issue was to remove both genera from CITES immediately arguing that no species of Dendrobatidae is considered threatened or endangered.

Arguing for the removal of any taxon from CITES II because there are no threatened populations is entirely circular. CITES II taxa are defined as "all species which although not necessarily now threatened with extinction may become so unless trade in specimens of such species is subject to strict regulation in order to avoid utilization incompatible with their survival" and "other species which must be subject to regulation in order that trade in specimens of certain species . . . may be brought under effective control." CITES I is for taxa that are presently endangered or threatened.

Bringsøe argues that inclusion of the entire genus into Appendix II is unnecessary as most species can be readily recognized and confusion should be rare. Although I have little experience with specimens of *Dendrobates* and *Phyllobates* in captivity, I have dealt with many different species of Boidae, *Iguana, Phelsuma, Cordylus, Varanus*, and Chamaeleonidae, all of which are protected under CITES Appendix II and most of which can be readily distinguished from congeners. The only exception noted for these taxa is that some species are CITES I; again, those taxa are readily recognized. Nevertheless, their trade is regulated under Appendix II to help curtail endangerment of species in the future. Yet, they are still imported as are *Dendrobates* and *Phyllobates*. It seems to be customary for CITES to list a higher taxon, such as an entire genus, under Appendix II if there is a high demand for trade in members of that taxon, such as *Phelsuma* in the pet trade, or *Varanus* in the skin trade. To insist upon the removal of any taxon from Appendix II when there is a clear trade market for that taxon is questionable. Bringsøe points out that dendrobatids are locally quite abundant in parts of the New World tropics. Yet it seems that the removal of any taxon from CITES II on the basis of local abundance is shortsighted. While no dendrobatid is currently listed as endangered or threatened, the habitat in which they occur could easily be listed as such and continued trade could put unnecessary pressure on those populations.

Bringsøe points out there is no evidence of range contractions in historic times for dendrobatids. However, in recent years *Dendrobates* have increased in popularity in the live animal trade (Bertram 1989). This increase in trade has almost certainly created a new pressure for existing populations. Therefore, the lack of evidence of range contraction in historic times seems to be a moot point. The question is, could trade lead to range contractions in the future?

Lastly, Bringsøe states that Charles Myers (American Museum of Natural History) collected 7600 *Dendrobates histrionicus* from a single population over a four-year period with no detrimental effects seen in the population. Bringsøe uses this study as an example of the resilience of dendrobatids. Furthermore, he states that the number of specimens Myers collected greatly exceeds the number of *Dendrobates* imported into the U.S. during 1985. However, the data are not available to support this claim. *Dendrobates* and *Phyllobates* were not listed on CITES until 22 October 1987. Therefore, the exact number of dart frogs imported during 1985 is not known by the U.S. Fish and Wildlife Service Office of Management Authority. Nevertheless, since these genera were listed, the number of live individuals imported has steadily increased with a peak of 1405 individuals in 1989 (55 of which were captive born in the Netherlands). Between 1987 and 1991 a total of 2372 (95 captive born) individual dendrobatids were legally imported. Whether the number imported in 1985 was less than 7600 cannot be verified. Having the family listed under CITES has at least made determining the number of specimens imported annually a simplified matter.



In short, I see nothing wrong with listing all species of *Dendrobates* and *Phyllobates* in CITES Appendix II so long as there continues to be a demand for them in the live animal trade. If such a time should come when they are no longer in demand, then perhaps a reduction in CITES status would be warranted. However, at present, removing *Dendrobates* and *Phyllobates* from CITES Appendix II would be counter-productive.

TECHNIQUES

Nonlethal Blood And Muscle Tissue Collection From Redbelly Turtles For Genetic Studies

There is increased interest in the development of nonlethal procedures for collecting blood and muscle tissue samples from fish and wildlife populations for genetic studies, particularly for endangered species (Smith et al. 1976). A variety of nonlethal blood collection techniques have been described for turtles (see Dessauer 1970; Frye 1991), ranging from relatively invasive cardiac puncture (Maxell 1979; Stephens and Creekmore 1982) to less invasive venapuncture of surface veins such as jugular (Jacobson et al. 1992), scapular (Avery and Vitt 1984), ventral caudal (Powell and Knesel 1992), and dorsal coccygeal (Samour et al. 1984). Collection techniques for muscle and other tissue samples from turtles range from killing the animal to taking samples from toe and tail clips. Because of their unique anatomy, turtles present challenges in both sample collection and restraint. Unlike birds and mammals, visualizing and stabilizing surface veins of turtles is difficult. It also often requires two handlers to collect a blood sample and/or mechanical restraint devices (Powell and Knesel 1992). While these techniques work well in laboratory or clinical situations, they are sometimes difficult to apply under field conditions, particularly when only one researcher is available. We present an alternate restraint technique that is easily used in the field and requires only one individual to both restrain the turtle and collect samples. We also discuss collecting blood from the dorsal coccygeal vein at a specific location, and a standard surgical procedure for taking muscle biopsies. These techniques were developed on redbelly turtles (*Pseudemys rubriventris*), but should be applicable to other freshwater turtle species.

Restraint.—To restrain redbelly turtles, we used four small rags (or paper towels) and one standard sized bath towel. Small rags were rolled into balls and placed into the cavities formed behind each leg when they are in complete flexion (i.e., withdrawn into the shell); rags were slightly larger than the size of the cavity. The pressure provided by these rags replaced digital pressure that would ordinarily be supplied by a second handler. We loosely wrapped the bath towel around the front half of the turtle to prevent visual stimulus, leaving the back half exposed. Both techniques resulted in passivity. To have both hands free to collect blood and muscle tissue samples, we placed the turtle between our legs with its head facing downward and carapace directed away from the handler's body. The turtle's head was then forced into its shell by gently placing it against a hard surface, such as the ground. With the turtle firmly grasped between our legs in this manner, both hands were left free—one to hold the tail and one to collect the samples.

Blood Collection.—After restraining the turtle, we collected blood by firmly grasping the turtle's tail with a gauze sponge for traction, pulling the tail out in straight-line extension, and flexing it over the plastron at a 90° angle. With the tail in this position, the turtle offered little resistence. We then collected a 1–3 ml blood sample from the dorsal coccygeal vein directly into syringes that were coated with sodium heparin (USP 1000 units/ml; ELKINS-SINN, INC.); however, lithium heparin is currently the recommended anticoagulant for reptiles (Jacobson et al. 1992). For small (<100 mm greater carapace length) turtles (N=60) we used a 1 ml syringe with a beveled 23 or 25 gauge needle; for large (>100 mm greater carapace length) turtles (N=140) we used a 3 ml syringe with a 21 gauge beveled needle. When a 3 ml syringe was used on small turtles, too much suction was created and the vein collapsed.

We discovered certain landmarks and positions that facilitated locating the dorsal coccygeal vein. First, the needle was inserted slightly to the right (or left) of the spinous process of the first or second caudal vertebrae at a 45° angle. Second, the tail must be fully extended before flexing it over the plastron and the vertebral spinous processes should be symmetrical. Finally, the needle should just touch the spinous process and then be backed off very slightly. Once blood appears, gentle suction that mimics the pulsating flow of the venous sinus should be applied for the duration of blood collection.

Muscle Plug Collection.—Before taking the muscle biopsy, we always instituted a local anesthetic nerve block at a site about 2 cm distal to the base of the tail midway between the spinous and transverse vertebral processes. Approximately 0.03 ml of a 0.1% lidocaine HCl solution (Burns Vet. Supply, Oakland, California) was injected into the muscle at five places to form a circle around the biopsy site. We tested whether anesthesia was present by pinching the site with forceps; if the turtle reacted, we injected additional lidocaine.

We followed standard aseptic surgical techniques (Knescht et al. 1981) by scrubbing the tail with betadine scrub and then liberally applying betadine solution (Purdue Frederick Co., Norwalk, Connecticut), followed by ethyl alcohol. The skin was picked up with forceps, and a longitudinal 1 cm incision was made through the skin using straight-straight scissors. The exposed flexor caudae lateralis muscle was then lifted up with the forceps, and a 1–2 mm longitudinal wedge was cut. After taking the muscle sample, the biopsy site was lavaged with 10% betadine solution and the skin sutured with 4-0 monofilament nylon (ETHICON) in an interupted pattern (Knescht et al. 1981). This standard surgical technique offers a safer approach than using a scalpel by reducing the possibility of cutting the muscle too deeply or severing a blood vessel.

After sample collection, all turtles were returned to their respective ponds of capture with the exception of turtles that were biopsied. These turtles were held overnight to ensure no systemic anesthetic effects before release.

We collected 200 blood and 40 muscle tissue samples from Massachusetts and New Jersey redbelly turtles for genetic studies during June and August, 1991. We observed no mortalities as a result of sample collection. Further, in August we recaptured two New Jersey turtles that had biopsies taken in June; both turtles' incision sites were completely healed with no observable signs of infection. Currently, we are using these same techniques to collect samples from spotted turtles (*Clemmys guttata*) for genetic studies.

Acknowledgments.—We are grateful to T. and A. Graham in Massachusetts, and A. Rich and A. Blades in New Jersey for their assistance with redbelly turtle field collections. This work was supported by U.S. Fish and Wildlife Service contract 50181-5236 and by the Massachusetts Division of Fisheries and Wildlife through the Biodiversity Conservation Program in the Department of Forestry and Wildlife Management, University of Massachusetts, Amherst.

Suggestions For Handling Museum Specimens Of *Phrynosoma* (Iguania, Phrynosomatidae)

Horned lizards, genus *Phrynosoma*, are among the most unusual of desert lizards because of their peculiar squat habitus and spiny armament. The cephalic horns vary in number, size, and orientation among several species, and therefore are diagnostically important. Also, geographic variation in horn size is apparent among populations of some species (e.g., *Phrynosoma douglasi*). Further studies of the cephalic horns of these lizards may reveal interesting information about ontogenetic and clinal (altitudinal and latitudinal) patterns of variation.

Museum specimens of horned lizards have been utilized extensively for systematic and ecological studies over the past few decades. Inevitably, preserved specimens have sustained some damage during handling. The tips of the occipital and temporal horns are especially susceptible to breakage when a specimen is placed (ventral side up) on the hard surface of a laboratory table during dissection or to take measurements. In a sample of 158 specimens known to have been used in previous studies, 71 (45%) sustained damage to the horns. The damage was more severe in specimens which had been dissected compared to those which had not. Unfortunately, such damage renders the specimen less useful (or useless) for studies of ontogenetic, geographic, and clinal variation in the length of the cephalic horns. I offer several suggestions to minimize the damage to *Phrynosoma* specimens during study and routine handling for packing and shipping.

A specimen selected for dissection, measurement, or study of the ventral squamation should be placed on a small Styrofoam platform (Fig. 1). The horns of the specimen will pierce the Styrofoam and the platform will support the specimen without damage to the horns. In order to be effective, however, the thickness of the Styrofoam must exceed the length of the horns. The most problematic species are large *Phrynosoma asio* and *P. cornutum* because their horns are quite long and have an upright orientation. In any case, I have found that a thickness of 17 mm (11/16 inch) is more than adequate for even the largest horned lizard. I routinely use a platform when taking measurements or studying preserved specimens under a dissecting microscope. A shallow, covered tray containing alcohol can be used to periodically moisten specimens during study. Live horned lizards used for simple surgical procedures in the laboratory, or field collected for taking snout-vent and tail length measurements, can also be placed on Styrofoam. I have found this material to be safe and effective during restraint of the lizard. A Styrofoam platform can be fashioned from the walls of a Styrofoam cooler, or obtained from insulated shipping containers. The latter often have square or rectangular pieces of suitable size.

Museum specimens packed for shipment are typically wrapped in cheesecloth, rolled, soaked in alcohol, and placed in plastic bags. Damage to the specimens during this process can be minimized by laying the specimens ventral side down on the cheesecloth. When the specimens are rolled into a bundle on the table top, the horns of the lizards will face inward and are less likely to contact the hard surface of the table, thereby avoiding potential damage. A series of specimens rolled in such a manner is also less likely to puncture the plastic bag and cause leakage of alcohol. Specimens of similar size should be bundled together as this will more effectively protect the horns than if specimens of mixed sizes are wrapped together.

Finally, the horns of preserved *Phrynosoma* can be damaged when the specimens are removed and returned to museum storage jars. They should, accordingly, be removed and replaced with care. Specimens which are situated against the glass sides of the jar are more susceptible to damage than those in the center. They should be oriented so that the ventral surface, rather than the spiny dorsal surface, is against the glass.

FIG. 1. A Styrofoam platform (19.5 x 19.5 x 1.7 cm) used to support *Phrynosoma* specimens during morphological study. Photograph courtesy of David H. Lewis.

Specimens in museum collections are an important resource for scientific research and public education. Museum specimens are becoming increasingly difficult to replace as more biological populations are lost through habitat destruction, and the enactment of protective legislation restricts the further collecting of threatened and endangered taxa. These considerations should be kept in mind when borrowing specimens for study.

An "Easy" Method To Remove Common Snapping Turtles (*Chelydra serpentina*) From Legler Hoop Traps

The Legler hoop trap (Legler 1960) is widely used to trap aquatic turtles. This trap and modifications of it utilize narrow openings ("throats") that can be fixed in size by tying off the throat loop which allows standardization of trap throat size. Once set, the throats cannot be easily untied to remove turtles. Consequently, turtles can only be removed by pulling them back through the narrow throat opening. With turtles of the genera *Chrysemys, Trachemys, Kinosternon*, etc., this is a simple task. However, clearing a trap can become difficult, dangerous, and time consuming with large specimens of the common snapping turtle (*Chelydra serpentina*). These large turtles defend themselves with alacrity and strike at any moving object, including the researcher or other turtles inside the trap at the time. A single bite can cause death or serious injury to smaller turtles caught along with the *C. serpentina*.

During the 1992 field season, I had much practice removing these animals from Legler hoop traps and a method evolved which made this task much easier and safer to accomplish. I have not seen this method in use anywhere else nor have I seen it described in the literature. Because this method makes removing *C. serpentina* from traps quicker, easier, and safer for the researcher and the other occupants of the trap it is described here.

After recovering and collapsing the hoop trap, it should be placed so that one of the throats is on the substrate and the other is on top of the resulting pile of hoops and turtles. The researcher then reaches through the upper throat and grasps the tail and posterior edge of the carapace of the first *C. serpentina* to be removed. The turtle is then upended with the head of the turtle down and with the plastron facing the researcher. With the turtle in this vertical orientation, it should be slowly pressed down upon the substrate (the ground if ashore, the bottom if in shallow water, or the deck if in a boat). In this manner, the head of the turtle is forced to withdraw into the carapace. Once the anterior part of the shell is flush with the substrate, the hind limbs of the turtle should be grasped with one hand so that the claws of each foot face one another. The researcher's other hand can then easily work the throat over the back of the carapace and down to the anterior portion of the carapace until all but the anteriormost part of the carapace is free of the netting. At this point, the turtle with the plastron facing the researcher is lifted free of the substrate. Because the turtle extends its head and neck out and towards the researcher at this point, the turtle is completely freed of the net except for the forelimbs. These can then be shaken loose from the netting. If more than one *C. serpentina* is in the trap, the carapace of the individual being removed should be rotated so that the carapace faces any other *C. serpentina* in the trap. Not only does this shield the researcher from the attentions of other *C. serpentina* but it protects the individual being removed from injuries inflicted by strikes of the other *C. serpentina* in the trap. Using this method, *C. serpentina* can be rapidly removed from traps with little risk of injury to the researcher or to the other turtles in the trap.

Acknowledgements.—I thank L. E. Brown for discussing the value of the method with me and D. Moll for reading a copy of the manuscript.

Tracking Small Animals With Thread Bobbins

Identifying the specific pathways of animal movements may be useful when trying to determine microhabitat and resource use (Dodd 1992), behavioral responses to habitat structure, and/or nesting sites of secretive animals. A technique that has been used to follow the direct routes taken by animals in the field is the spool-and-line tracking method (e.g., Broughton and Dickman 1991; Miles et al. 1981). Previously, this technique incorporated a rotating spool of thread that was attached to the animal on a trailing device which allowed the spool to unwind as the animal moved (Miles 1976). The method was improved by using a quilting cocoon of thread (cocoon bobbins) which allowed the thread to unwind from the center of the spool rather than rotate off the outside of the spool (Miles et al. 1981). Researchers using spool-and-line tracking enclose the thread bobbins in some type of container, such as plastic tubing. This type of encapsulation of the thread bobbin adds considerable weight and bulk which may overburden or hinder free movement of small animals. Also, it has been difficult to find a readily available source for obtaining the bobbins in the U.S.

Here, I provide the address of a U.S. company that currently manufactures thread bobbins and information on a quick and easy method of encapsulating them that adds very little weight or bulk. Bobbins can be purchased from Culver Textiles, P.O. Box 360, West New York, New Jersey 07093, USA (tel. 800-526-7188 or 201-866-6200 in New Jersey). Currently, two sizes of thread bobbins are available from Culver Textiles: a small bobbin that is 4 cm long and 1 cm wide and weighs approximately 1.8 g uncoated and 2.3 g coated; and a large bobbin that is 5 cm long and 1.5 cm wide and weighs approximately 4.5 g uncoated and 5.3 g coated. I encapsulate the thread bobbins in the following way: (1) I pull about a meter of thread from the center of the bobbin to ensure that the thread line is free-moving. (2) I wrap the bobbin in clear plastic wrap (e.g., Saran Wrap™), twist it at the bottom of the bobbin, and tape it to the side of the bobbin (Fig. 1). (3) Using forceps, I hold the protruding plastic wrap from the thread end of the bobbin and dip the bobbin in plastic dip (Plasti Dip™, used for dipping tools, is available in several colors in most local hardware stores). (4) I place the coated bobbin on a piece of waxed paper and allow it to dry. The flat surface that is formed while the bobbin is drying facilitates attachment of the bobbin to the animal (especially turtles). I have used this technique successfully in tracking striped mud turtles, *Kinosternon baurii*, to their nesting sites.

A Method For The Restraint And Transport Of Crocodilians

Devices for restraining and transporting crocodilians include cargo netting, ropes, squeeze cages, and planks to which the animals are tied (Fowler 1978). None of these devices are without drawbacks in working with American alligators (*Alligator mississippiensis*) in the wild. Our specific concerns are to reduce further stress to an animal after the stress of capture, protect it from the direct heat of the sun, keep it immobile to prevent injury to the animal or its handlers, and allow for ease of collecting data (e.g., taking measurements, ascertaining sex, attaching tags, collecting blood from the cervical or caudal regions). A technique was developed to address these concerns that is similar in concept to the method developed by Murphy (1971) for restraining snakes within acrylic tubing.

We utilized a white PVC pipe (50 pound plastic irrigation pipe) to contain the alligator and ropes to secure and maneuver the anterior and posterior portions of the body. The pipe had an inside diameter of 0.31 m, a wall thickness of 0.32 cm, and was cut to 3.0 m in length. Holes of a diameter sufficient to allow the passage of a rope without binding were drilled along the length of the pipe at intervals of 15.2 cm. The dimensions given for the pipe are suitable for adult American alligators up to 3.0 m in total length and other similarly-sized crocodilians. If smaller species/individuals are to be dealt with, a smaller size diameter and length of pipe would be desirable to increase maneuverability and reduce the space surrounding the animal while it is in the pipe. Conversely, with extremely large individuals, a pipe of greater diameter and length would be appropriate.

The procedure begins by noosing the crocodilian around the neck with a rope (Fig. 1a), either as a form of capture or after being captured by another means such as a snare trap (Murphy and Fendley 1974). The end of the noose rope is passed through the pipe (Fig. 1a), and the pipe is guided over the animal's head. Once the head is inside the pipe, constant tension is applied to the rope to hold the pipe in position, and the pipe is rotated so that the holes are on the top. The forelimbs are folded back against the body by the pipe, as the animal is pulled into its lumen until the back legs come even with its end (Fig. 1b). A second rope is then tied immediately anterior to the back legs (Fig. 1b). By pulling on the anterior or posterior rope the animal can be positioned exactly within the pipe, or so that the head or caudal region extends from an end of the pipe for a desired distance. If access is required to the head region, a rubber bicycle inner tube is tied around the snout to keep the jaws closed (Fig. 1c). Once the animal is positioned, each rope can be secured through a nearby hole and tied in a knot (Fig. 1d). The tension on the ropes should restrict forward or backward movement within the pipe but allow enough freedom so that the animal can move its head up and down to prevent regurgitated stomach contents from blocking the glottis. The procedure can be accomplished with two people. However, additional personnel may be needed for lifting the crocodilian into a vehicle for transport.

The regularly-spaced holes in the pipe can aid in measuring total and snout-vent lengths, as well as providing places to secure the ropes. The holes allow the snout and tail tips to be seen; thus a tape measure can be placed on top of the pipe to get an accurate measure of total length. Moreover, if the tip of the snout is positioned at the exact end of the pipe, much of the measurement can be calculated without the use of a tape measure, by knowing and/or marking on the pipe the distance between holes. Snout-vent length can be determined by lining up the end of the cloaca with the end of the pipe and measuring forward.

To release the animal, the rope near the tail is removed first (Fig. 2a). The animal is then pulled to the front of the pipe, until the rope on the neck can be released (Fig. 2b). The inner tube securing the jaws is removed by pulling it off with a snake hook rather than untying it (Fig. 2b), and then the pipe is tipped upward and/or jerked backwards/upwards, until the animal is induced to leave it (Fig. 2c).

This technique has been used successfully on American alligators in the wild at Brazos Bend State Park, Ft. Bend Co., Texas since 1990. We believe it has significantly reduced post-capture stress to the animals and has increased safety to both the animals and their handlers. The animal cannot hurt itself once restrained in the pipe, and because the legs are folded back rather than tied there is not the potential problem of restricting circulation to the limbs. It is not necessary to cover the animal's eyes while it is in the pipe, but we do drape a cloth over the eyes if we have the head positioned outside the pipe. The only difficulty that we have encountered with the technique is that some individuals begin to roll after they are noosed and this makes it somewhat difficult to get them started into the pipe. However, once the head is inside the pipe it is not a problem to pull the rest of the body inside.

The pipe diameter and length that we utilized was chosen to accommodate a varying size range of adult alligators. However,

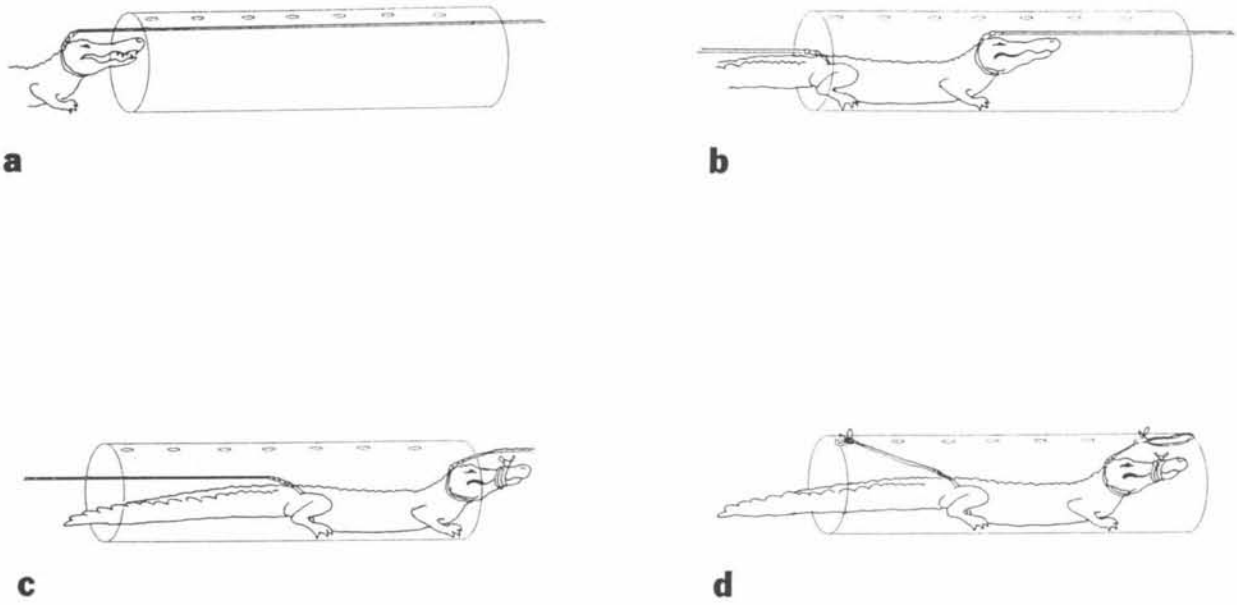

FIG. 1. Restraining the crocodilian in the pipe. (a) Pulling the noosed crocodilian into the pipe. (b) Attaching a rope in front of the hind legs. (c) Positioning the crocodilian within the pipe. (d) Securing the ropes.

if smaller crocodilians were to be handled exclusively, then a shorter pipe with a smaller diameter would be preferable to reduce the weight and increase maneuverability. Because PVC plastic deteriorates from extended exposure to UV light, the pipe should be stored out of direct sunlight.

Although the technique has not been tested on crocodilians in captivity, we believe it could be applied to farm or zoo settings as well. Since preparing the initial draft of this manuscript, we have been made aware of two instances where pipe has been used as a restraint and transport device for crocodilians. In the early 1980's some crocodiles were shipped to the U.S. inside PVC pipes (L. Brandt, pers. comm.). Also, a photograph in Alderton (1991) shows a juvenile alligator being placed into a corrugated drain pipe with a caption stating that the pipe was filled with young alligators to transport them safely.

The Use Of Leverage To Facilitate The Search For The Hellbender

During September 1991, we searched for hellbenders (*Cryptobranchus alleganiensis alleganiensis*) in the New York portion of the Susquehanna River drainage. The purpose of this survey was to attempt to verify previous records (Bishop 1941; Bothner 1981; Breisch 1990) and to find new localities and potential habitat.

Many methods have been tried to locate hellbenders including visually searching, electroshocking, and rock-lifting (Williams et al. 1981). We tried visually searching both day and night and electroshocking with a Smith-Root model 11-A (Smith-Root Inc., 14014 N.E. Salmon Creek Ave., Vancouver, Washington 98665, USA) with no hellbenders being located using those methods. We tried to trap hellbenders using 0.6 m by 0.6 m by 0.2 m high wire mesh traps baited with chicken livers with the same results. This left us with only the rock lifting method to try.

As hellbenders are normally found under large rocks in riverine situations, a technique was devised to enable two people to quickly lift large rocks with as little back strain as possible and without destroying the habitat. Anyone who has ever looked for hellbenders should be able to appreciate the difficulty of bending over or kneeling to hand lift large rocks in 10-15°C water.

A device available in forestry supply catalogs (e.g., Forestry Suppliers Inc., P.O. Box 8397, Jackson, Mississippi 39284-8397, USA) called a peavey was used to lift the chosen rocks. As the peavey is normally used to roll heavy logs in the 0.3–0.75 m diameter range we thought that this device would be both inexpensive and sturdy enough to safely lift large rocks. One person using a single peavey was able to lift rocks measuring up to 1.25 m by 1.85 m by 0.25 m thick. The hook on the peavey was caught on the underside of the rock or on any irregularity on the side of the rock. The person doing the lifting would then hold the end of the 1.3 m handle, bend at the knees, and then lift with a straight back. The second person would then probe under the rock with a long-handled dipnet to attempt to dislodge any hellbender that might be hiding under the rock. Rocks were lifted upward from the downstream edge just far enough to allow a dipnet to be passed under the rock. No attempt was made to flip the rocks completely over as it was desirable to have as little effect on the habitat as possible. In most cases the upper edge of the rock just barely broke the surface of the water. As this survey was done during the hellbender nesting season we choose to lift the rocks from the downstream edge in order to minimize effects on any nests that might be present. At other times of the year lifting the rocks from the upstream edge will allow the current to quickly clear disturbed sediment and make locating hellbenders easier.

Another advantage of using the peavey is that searching in relatively cold deep water is possible. We were able to lift rocks and verify the presence of hellbenders in water depths of up to 1 m without getting anything more than our chestwaders and hands wet. This method can be used during any season of the year without undue discomfort on the part of the users. One must be cautious during the nesting season to minimize nest disturbance.

The peavey is inexpensive ($49.95 Forestry Suppliers) and much safer to use than electroshocking. Electroshocking equipment can cost over $2000 and requires safety gear to be worn. A word of caution is in order. Do not try this method by yourself. It is estimated that many of the rocks we lifted weighed 275–450 kg We used two people (one netting and one lifting) and found that in some cases that was not enough. In one case a hellbender escaped to the left while the netter was to the right and the lifter attempted to pursue the hellbender while pushing away a rock in the 350-450 kg range. The best way to utilize the peavey is with a crew of at least three persons. One person lifts the rock and does not pursue anything while the others attempt to capture hellbenders either by dipnet or seine.

This method was successfully used to move many thousands of kg of rocks over six days of searching and resulted in the location of 33 hellbenders and five hellbender nests. Many old sites were verified and almost 50 km of river were added to the known range of *C. alleganiensis* in New York. A big advantage of the peavey was the relative ease in which rocks could be lifted in a controlled manner. This enabled us to put all nests discovered back together (with eggs and attending male). Only one animal discovered using the peavey technique was injured and this injury was a scraped front foot that should heal quickly.

This method was further put to the test during a one-day search for hellbenders on 17 November 1992 during which it snowed almost constantly with an air and water temperature of 2°C. One hellbender was located. This search was hampered by both the weather and high water conditions. Without the peavey it would have been very difficult to locate any hellbenders.

HERPETOLOGICAL HUSBANDRY

Cannibalism In A Captive West African Bush Viper (*Atheris chloroechis*)

On 28 September 1992 at the Audubon Zoological Garden, an adult male West African bush viper (*Atheris chloroechis*) was introduced into a large exhibit containing two adult female conspecifics. The exhibit measured 152 x 91 x 91 cm, and was furnished with climbing branches and a gravel substrate. All specimens were healthy, long-term captives and had previously been together from 3 December 1991, through 28 January 1992, without incident. On 9 October 1992, the male was missing, and it was presumed that he had been consumed by a female whose body was distended almost its entire length. The female had a SVL of 66 cm, and weighed 161 g. Each snake had been accepting live three-week old mice (*Mus musculus*) on a weekly basis, and there were no food items in the enclosure at the time of the incident.

Cannibalism in arboreal vipers has been reported in captive *Atheris squamiger* (Wallach 1980), and *A. superciliaris* (Broadley 1983), as well as *Trimeresurus wagleri* and *Bothriechis schlegelii* (Bridegam et al. 1990). Previous accounts of cannibalism or ophiophagy in captive *A. chloroechis* have not been reported.

Wild *A. chloroechis* are opportunistic feeders, preying upon birds, small rodents, lizards and frogs (Cansdale 1961), but are not known to include snakes in their diet. Typically, these snakes ambush prey while hanging concealed amid branches, with the head often lower than the prehensile tail. As is typical with this species, the prey is bitten and held until dead before swallowing.

This occurrence of cannibalism may be interpreted as aberrant behavior; however, caution should be exercised during introductions with *A. chloroechis* or any of its congeners.

A Radiographic Sexing Technique For *Heloderma suspectum*

Sexual dimorphism is not at all apparent in *Heloderma suspectum* despite Laszlo's (1975) and Tinkham's (1971) description of differences in head size and scalation. Methods currently utilized for sexing *H. suspectum*, such as probing (Laszlo 1975; Wagner et al. 1976), are inconclusive. Visualizing sex organs with a fiberoptic laparoscope, although reliable, involves invasive procedures. The method of injecting saline solution into the hemipenial area to promote eversion has proven somewhat successful, but requires anesthesia (L. DeNardo, pers. comm.). Captive reproduction of this species has occurred at several institutions (Lamont 1987; Peterson 1982; Wagner et al. 1976), but a reliable method of sex determination was not mentioned in those reports. In this note we describe a non-invasive osteometric method to determine sex by revealing gender differences in ischial length and width. Intraspecific structural variation occurs

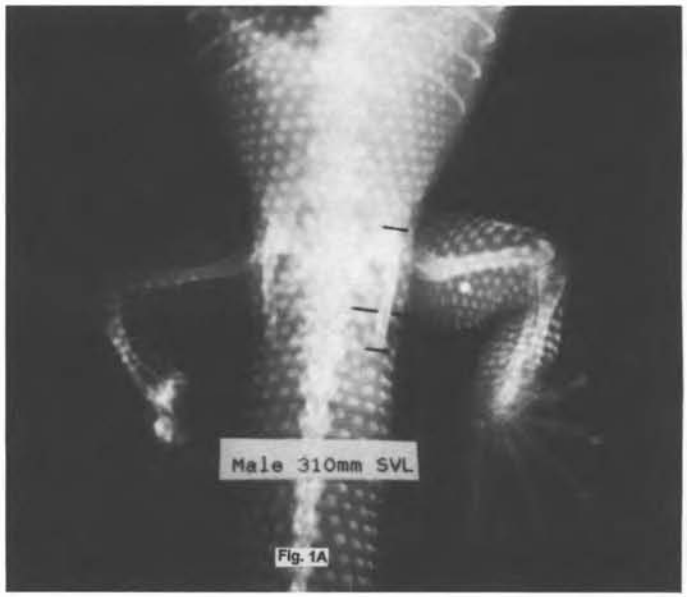

FIG. 1. Radiographs of (A) male and (B) female *Heloderma suspectum* indicating measurements for length and width.

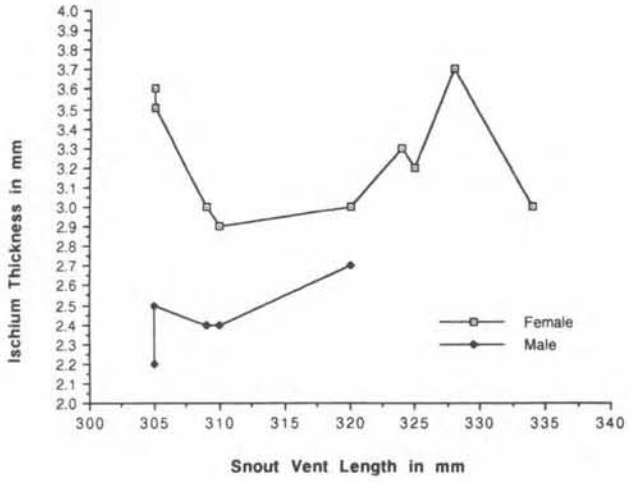

Fig. 2A

FIG. 2. Graphs showing separation of sexes by (A) ischium thickness and (B) ischium length.

in the pelvis of certain mammals (Becker 1954; Cornwall 1956; Dunmire 1955; Gardner 1936; Guilday 1951; Krogman 1962; Taber 1956), but has not been documented for other groups of vertebrates.

Radiographs from seven live specimens of *H. suspectum* were examined. Radiograph dosages were KVP 40, mass 75 @ 1/60 of a second (3M standard veterinary x-ray film). Seven skeletal preparations of known sex were also examined to substantiate data from radiographs (see Appendix 1). All measurements were made to the nearest 0.1 mm using dial calipers. Only the ischial arm could be accurately measured from radiographs. The magnification of the radiographic image was assumed to be minimal since the film was placed directly under the pelvic region.

Two measurements were made: the length from the posterior angle to the anterior angle of the ischium, and maximum thickness of the ischium (Figs. 1a, 1b). By plotting the first measurement against snout-vent length (SVL), and the second measurement against SVL for both sexes (Figs. 2a, 2b), males were clearly differentiated from females. Student t-tests were used to determine the statistical significance of the gender differences (for thickness, $t=5.53$, $df=12$, $P<0.01$; for length, $t=3.45$, $df=12$, $P<0.01$).

To determine pelvic girdle differentiation during ontogeny, a radiographic record of a group of 3 sub-adult *H. suspectum* was made. These specimens were radiographed at 2 weeks, 24 weeks, and 36 weeks post hatching. At 36 weeks, gender differentiation in these individuals becomes discernible in both measures (Table 1).

TABLE 1. Radiographic history of sub-adult *Heloderma suspectum*.

Specimen No.	Sex	SVL	Ischium Length	Ischium Thickness
2 wks				
304	?	92	6.2	1.5
309	?	102	7.0	0.9
307	?	90	7.5	1.4
12 wks				
304	?	145	8.1	1.6
309	?	152	11.0	1.2
307	?	146	10.7	1.7
36 wks				
304	M	215	13.9	1.7
309	F	209	18.6	2.1
307	F	198	17.2	2.0

Specimens of similar size should be used when making comparisons, as differentiation in ischium length is not apparent between large males (>450 mm SVL) and small females (<250 mm SVL). However, ischium thickness is closer to being unequivocal for sex determination. This character is greater in females than in males, provided that animals are at least 300 mm SVL.

Symptoms Of Gas-bubble Trauma In Two Species Of Turtles, *Chelydra serpentina* And *Apalone spinifera*

Gas supersaturation in aquaculture systems can be caused by any one of a variety of situations. These include entry of air into the suction side of a pump (Marsh and Gorham 1905), photosynthesis (Renfro 1963; Woodbury 1941), and use of well or spring water (Gorham 1901; Weitkamp and Katz 1980).

Heating of gas-saturated water has also been shown to cause gas-supersaturated water in aquaria (Marsh and Gorham 1905), culture tanks (Lightner et al. 1974), cooling-water outfalls of power plants (DeMont and Miller 1971; Marcello and Strawn 1972), fish hatcheries (Rucker and Hodgeboom 1953), and salmonid hatching containers (Zirges and Curtis 1975). Malouf et al. (1972) observed gas supersaturation resulting from heating cold seawater in closed heat exchangers.

Gas-bubble trauma (GBT) has long been recognized as a problem for fish (e.g., Gorham 1901; Marsh 1903). Gas supersaturation has also produced symptoms in shrimp (Lightner et al. 1974), crabs (Johnson 1976), and other gill-breathing invertebrates (Malouf et al. 1972; Nebeker 1976). Amphibians are also susceptible to gas-bubble trauma (Colt et al. 1984a; Colt et al. 1984b).

Symptoms of GBT include erosion of fins due to bubble formation in capillaries, exophthalmia, subcutaneous emphysema of the head, inability to remain submerged (Colt et al. 1984a), bubble formation in the epidermis and viscera, hemorrhage (Weitkamp and Katz 1980), equilibria disturbance, cessation of feeding, hemostasis, and death.

I am unaware of reports of reptilian species exhibiting symptoms of GBT. In this paper, I report symptoms of GBT in two species of turtles, the common snapping turtle (*Chelydra serpentina*) and soft-shelled turtle (*Apalone spinifera*).

Approximately sixty, one-year-old common snapping turtles were held in an indoor culture system supplied with city water. The system consisted of six plastic trays (91.44 cm x 182.88 cm x 15.24 cm) with a flow-through water supply. Turtles were held in plastic containers (50 cm x 35 cm x 22 cm) within these trays. The containers had four 0.95 cm holes drilled into the bottom and were suspended above the tray bottom on sections of 1/2" (21 mm od) PVC pipe.

Approximately 7.5 cm of water was maintained in the containers by a central standpipe in each tray. City water (22°C) heated to 29°C with a commercial water heater was supplied continuously to the individual containers. The turtles did not have access to dry substrate and were unable to leave the water.

Symptoms appeared approximately one week after turtles were introduced into the system. Gaseous lesions developed under the skin of the feet and neck causing the animals to float (Fig. 1). The feet became grossly distended and many of the affected animals eventually lost their claws. This was apparently due to loss of blood supply and subsequent soft-tissue necrosis. Lesions were also prominent around the cloacal opening, causing distention and hemorrhaging. Several of the turtles eventually died.

Animals exhibiting pathology were sent to the Louisiana State University School of Veterinary Medicine for examination. Dead and live turtles exhibiting pathology were analyzed. Bacterial analyses were performed with only *Citrobacter freundii* and *Proteus vulgaris* being identified. These two species have not been shown to be gas producers.

All of the one-year-old common snapping turtles were removed from the culture system and placed into a fiberglass holding tank which was raised at one end. Ambient city water (22°C) was introduced into the lower end of the tank, leaving sufficient space to allow the turtles to leave the water. Within 48 h, all symptoms had disappeared. The turtles resumed normal behavior and began feeding. Schiewe (1974) showed that recovery of fish from sublethal exposure to gas supersaturated water can be rapid.

Subsequently, hatchling common snapping turtles (315) were stocked into the flow-through culture system for a feeding trial. Within four days, over 50% of the hatchlings exhibited GBT-related pathology. These turtles were removed from the culture system and placed into a plastic tub with approximately 1.27 cm of water. Within 24 h, all symptoms disappeared and the hatchlings resumed feeding.

FIG. 1. Common snapping turtles exhibiting symptoms of gas-bubble trauma. Note involuntary floating and distended limbs and neck. Unaffected turtle can be seen submerged on lower left.

Tropidophis semicinctus Gundlach and Peters, 1865

74. *Tropidophis semicinctus* (Photo by Vlad T. Jirouhek)

Type-locality: Cuba.
Syntypes: ZMB 5076.
Description: Maximum total length about 460 mm; habitus slender; dorsal scale rows at midbody 21, 23, or 25; dorsal scales smooth or slightly keeled; ventrals 203-214 in males, 201-213 in females; supralabials 8-11; infralabials 9-12; subcaudals 34-39 in males, 34-40 in females; preoculars 1/1; postoculars 3/3.

The head is chestnut brown, and the dorsal ground color is yellow to orange. The body blotches are dark brown to black, 19-29 in number, in two discrete series (with a tendency to fuse on the neck). The dorsal pattern gives the impression of alternating pale and dark bands. An orange to brownish vertebral stripe (5-6 scales wide) is often present. The supralabials and throat are yellowish. The tail has 3-9 blotches. The venter is immaculate.
Distribution: Western and central Cuba; Pinar del Rio Prov. (Rancho Mundito; Soroa) east to Sancti Spiritus Prov. (northwest of Trinidad; Casilda), north to Matanzas Prov., and to near Sagua la Grande, Villa Clara Prov., in the northeast.
Natural History:
Habitat - Mesophilic; Darlington (1927) collected two under a rock with *Anolis*.
Reproductive notes - Petzold (1969) reported newborn *T. semicinctus* with total lengths of about 160 mm and body masses of 1.5 g.
Remarks: Defensive behavior includes rolling into a ball with the head tucked away, autohemorrhaging (Darlington, 1927), and expulsion of an offensive anal secretion (Barbour and Ramsden, 1919).

The 1993 Herpetological Index

An Index to over 1700 Herpetological papers published during 1993. Although most of the articles are from professional journals, over 1/3 are from regional herp societies and herpetoculture magazines. The index is available in three formats: Book; Macintosh EndNote file; and Macintosh text file. All three versions are $10.00 (+ $2.00 S/H).

Similarly, hatchling soft-shelled turtles were placed into one of the flow-through containers and symptoms of GBT appeared within 24 h. Large bubbles emerged from the feet and neck as with the snapping turtles. Large bubbles also arose from around the eyes and carapace causing inflammation to the surrounding tissue. All soft-shelled turtles exhibiting these symptoms died within 36-48 h.

Heating of water in closed systems has been shown to cause gas supersaturation in fish culture systems. In the situation described in the present study, it could be assumed that the incoming water was saturated with gases before entering the water heater. With the increase in water temperature and the inability of dissolved gases to come out of solution in the water lines, it follows that the heated water introduced into the turtle containers was supersaturated with dissolved gases. These dissolved gases produced the symptoms observed in the turtles.

To remedy the problem, the culture system was modified by tilting the containers, allowing a small amount of water to collect in the lower third of the plastic container. This modification allowed access to dry areas in the container. The system was further modified by the addition of a timer and an electronically-actuated valve to control the water supply. Heated city water was added to the containers for five minutes at eight-hour intervals with this timing system. Water in the lower third of the container was flushed out with the incoming fresh water and exited through holes in the container bottoms. Following these modifications, no further gas-bubble pathology has been observed in more than 10 months of continual use.

Investigations to fully describe the effects of gas-bubble trauma on aquatic reptiles are under consideration. These findings would be especially important to the emerging aquaculture industries for these animals.

Acknowledgements.—I wish to thank the Louisiana Agricultural Experiment Station for the support of the facilities required. I also thank Dudley D. Culley, Jr., Robert C. Reigh, and Terrence R. Tiersch for their critical review of this manuscript.

NATURAL HISTORY NOTES

Natural History Notes (formerly Life History Notes) is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Longevity, Morphology, etc.). Use of figures to illustrate any data is encouraged, but should **replace** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send two copies of manuscripts, double-spaced, directly to the appropriate section co-editor (addresses on inside front cover). Manuscripts concerning reptiles should be sent to Lee A. Fitzgerald; those concerning amphibians should be sent to Randy D. Jennings.

Standard format for this section is as follows: SCIENTIFIC NAME (in caps), COMMON NAME (lower case, in parentheses) as it appears in Collins (1990. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 3rd ed., Herp. Circ. 19:1-41), KEYWORD (in caps). DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (Name(s) in caps, and address(es) in full). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

CAUDATA

RHYACOSIREDON LEORAE (NCN). **SIZE.** Taylor (1943. Univ. Kans. Sci. Bull. 29:343–361) reported maximum body size for a female *R. leorae* as 98 mm SVL and 207 mm total length. On 12 August 1993 we captured a female *R. leorae* (JLE00307) in a small stream near Río Frio, México, México at 3210 m elevation. The salamander was in a shallow pool (10 cm deep x 1 m wide) with slow circular movement and a water temperature of 13.2°C. Upon preservation, the salamander measured 103 mm SVL (to medium point of cloaca or 100 mm SVL to anterior point), 233 mm total length, and 62.0 g live wet body mass.

TESTUDINES

APALONE FEROX (Florida Softshell). **DIET.** *Apalone ferox* is the largest North American softshell, with a maximum reported size of 29.48 kg (Allen 1982. Herpetol. Rev. 13:49). Dalrymple (1977. J. Herpetol. 11:255–285) examined digestive tracts from 96 *A. ferox* and found the diet was comprised predominantly of snails, insects, and fish. Wright and Funkhouser (1915. Proc. Acad. Nat. Sci. Phila. 67:107–192) reported that "according to the natives the larger specimens devour also such water fowl as are unfortunate enough to be taken unaware by these reptiles." Dalrymple (*op. cit.*) found that one small male had eaten "a moderate sized passerine bird," but it is not known whether the bird had been captured or scavenged.

In the early afternoon of 24 July 1987, one of us (MBE) observed a large Florida softshell take a juvenile tricolor heron (*Hydranassa tricolor*) at Guana River Wildlife Management Area, Saint Johns County, Florida. The bird was in obvious distress when first seen standing in shallow water at the edge of a ditch, and it soon became apparent that a large softshell was holding it by the lower leg and attempting to pull it to deeper water. The water was too shallow to allow the turtle to pull the bird under, and a struggle continued for ca. 20 min (Fig. 1). Finally, a second large softshell joined the fray. The bird finally drowned when its head was submerged by one of the turtles. The total period of observation was ca. 30 min. This is the first unequivocal documentation of predation by *A. ferox* on birds. We can only speculate on the method used to catch the bird initially, but softshells frequently lie buried in the sand in shallow water, and the bird may have been ambushed when it stepped in front of a buried softshell.

FIG. 1. *Apalone ferox* struggling with a tricolored heron. The carapace of the turtle is visible to the left. The light "?" in the center is the white venter of the bird's neck. The bird is attempting to spear the turtle with its bill.

APALONE SPINIFERA (Spiny Softshell). **EXTREME KYPHOSIS.** An adult female *Apalone spinifera* was captured by a local fisherman on approximately 22 June 1993 while it was crossing Moon Lake Road, between Michigan Center Lake and Little Olcott Lake, in Jackson County, Michigan. Although normal in most respects (CL=241 mm, mid body CW=229 mm), the turtle exhibited extreme kyphosis (maximum total height= 127 mm, Fig. 1). It otherwise appeared to be in good health. I unsuccessfully attempted to induce oviposition using oxytocin on 9 July 1993. However, a clutch of hard-shelled eggs was laid on 10 July 1993, but unfortunately they were oviposited in water and destroyed. It was not possible to determine exactly how many eggs were laid or if they were fertile. The animal was later released at the capture site. Photographs and radiographs were deposited at the UMMZ.

Radiographs confirm external observations that the vertebral column was dramatically arched and directly underlies the carapace throughout the deformity. There were no organs or other defined tissues visible within the hump.

Extreme kyphosis has been previously documented in at least three Trionychidae species (two *A. spinifera* and one *A. mutica*: Smith 1947. Univ. Kansas Pub. Mus. Nat. Hist. 1:117–124; one *Lissemys punctata*: Duda and Gupta 1977. Herpetol. Rev. 8:119–120).

I thank Tom Hodgson of the Dahlem Nature Center for bringing this turtle to my attention. Doug Nelson generously contributed his time for the radiographs.

CARETTA CARETTA (Loggerhead). **GROWTH and PELAGIC MOVEMENT.** Carr (1986. BioScience 36:92–100) proposed that loggerhead hatchlings from the southeastern U.S. nesting beaches become incorporated in oceanic gyres and are carried to the eastern Atlantic. The hypothesized path of travel passes through the Azores, Madeira, Canary Islands, and, possibly, the Cape Verde Islands, and then back to the western Atlantic. The movement of a juvenile loggerhead on one portion of this path—from Madeira to the Canary Islands—has been documented. The loggerhead was one of many sea turtles tagged in the eastern Atlantic by a joint project of the University of Florida and the International Fund for Animal Welfare. On 29 June 1990, the crew of the *R/V Song of the Whale* placed two plastic tags (Jumbo-Roto tags, Dalton Ltd., Oxfordshire, England) on a loggerhead captured in the waters near Madeira (34°05'N, 17°21'W). The turtle had a curved carapace length (CCL) of 40.5 cm. On 4 February 1993, the turtle was captured on a longline of a Spanish vessel in the waters around the Canary Islands (29°46'N, 13°05'W). Both tags were still in place. The turtle was taken to Algeciras Bay, Spain, where an observer from the Centro Oceanográfico de Málaga recorded its straight carapace length (SCL measured from nuchal notch to posterior tip) as 46.0 cm. The turtle was held for two weeks, but did not feed. It was released alive but in poor condition in Algeciras Bay.

During the 950 days at large, the turtle moved a minimum distance of 610 km. To determine growth rate, 40.5 cm CCL was converted to 37.0 cm SCL as in Bolten et al. (1992. Herpetol. Rev. 23:116), yielding a growth rate of 3.5 cm/yr. This rate is slower than the 3.7 cm/yr rate reported for a smaller pelagic loggerhead in the eastern Atlantic (Bolten et al., *op. cit.*), but growth in carapace length usually decreases with increasing length (Bjorndal and Bolten 1988. Copeia 1988:555–564). The logistic and von Bertalanffy growth models developed for Florida loggerheads by Frazer and Ehrhart (1985. Copeia 1985:73–79) predict growth rates of 3.3 cm/yr and 6.4 cm/yr, respectively, for the size interval of loggerheads reported here. The measured growth rates are closer to those predicted by the logistic model for both our observation and for that of Bolten et al. (*op. cit.*). These slow growth rates suggest that the pelagic, juvenile stage of Atlantic loggerheads may span many years.

We thank José Carlos Santana (Centro Oceanográfico de Canarias, Instituto Español de Oceanografía) for his assistance. This work is supported by the Marine Entanglement Research Program of the U.S. National Marine Fisheries Service and by the International Fund for Animal Welfare.

BOLTEN,** Center for Sea Turtle Research, University of Florida, Gainesville, Florida 32611, USA, **JONATHAN GORDON**, International Fund for Animal Welfare and Wildlife Conservation Research Unit, Department of Zoology, Oxford University, Oxford, England, and **JUAN A. CAMIÑAS** Centro Oceanográfico de Málaga, Instituto Español de Oceanografía, 29640 Fuengirola, Spain.

ERETMOCHELYS IMBRICATA (Hawksbill). **REPRODUCTION**. On 20 June 1992 at Ostional National Wildlife Refuge, Santa Cruz, Guanacaste, Costa Rica, we observed a female *Eretmochelys imbricata* come ashore at 1615 h. This locality is known as the El Rayo sector of beach (10°00'N, 85°43'W), and is 2 km north of the main beach utilized for nesting by Pacific ridleys (*Lepidochelys olivacea*).

The female hawksbill measured 82 x 70 cm curved carapace length and width, and 60 x 53 cm curved plastron length and width. There was no evidence that this turtle had been previously tagged. She crawled to 25 m above the tide limit to the border of vegetation dominated by *Bromelia pinguin*, and selected a nesting site only after moving and presumbly smelling the substrate along a distance of 23.4 m parallel to the vegetation. She also attempted to move into the vegetation. Nest construction followed and 120 eggs were laid. Times noted for nesting activities were as follows: active search for nesting site, 60 min; nest cavity construction, 9 min; egg-laying, 12 min; filling-in the nest cavity, 10 min, for a total of 91 min.

The nest was subsequently protected by a wire cage measuring 40 x 40 x 25 cm. While installing the cage, we discovered another *E. imbricata* nest containing eggs in an advanced embryonic stage. Species determination was made by examination of an embryo. This second nest was reburied and left unprotected. It was preyed upon by dogs ten days later. The incubation period in the protected nest lasted 60 days, with 89 hatchlings found, yielding a hatching success of 74.2%. This is the first report of nesting for *E. imbricata* at this site.

MACROCLEMYS TEMMINCKII (Alligator Snapping Turtle) and ***CHELYDRA SERPENTINA*** (Common Snapping Turtle). **AGONISTIC BEHAVIOR**. In July 1991, we observed two *C. serpentina* that had emerged from a partially submerged brush pile in Onion Creek, Montgomery County, Kansas. The turtles, both probably juveniles (Bury 1979, *In* M. Harless and H. Morlock (eds.), Turtles: Perspectives and Research, pp. 571–602. John Wiley & Sons, New York) were found one day apart with bites presumably inflicted by a 24.7 kg female *M. temminckii* that was the subject of a biotelemetry study (Shipman 1993. Unpubl. M.S. Thesis, Emporia St. Univ., Emporia, Kansas. 90 pp.).

The first *C. serpentina* was found lying on the bank of the creek opposite the brush pile at 2000 h on 8 July. The inferred interaction was not directly observed, however a blood trail from the *C. serpentina* led to the location of the *M. temminckii* in the brush pile 10 m away. One of us (DB) had passed this site less than one hour earlier, and the *C. serpentina* was not there at that time. The second turtle was found at approximately the same time and location on the following day. Pattern and size of both bite marks matched those of a museum specimen *M. temminckii* skull of like proportions to that of the alligator snapping turtle in the creek. The bites were also similar in their location on the left posterior margin of the carapace (Fig. 1).

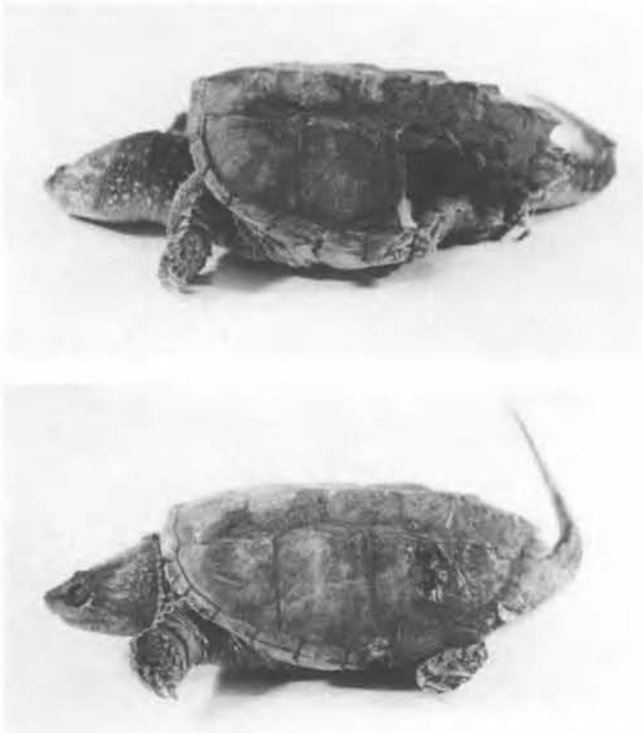

FIG. 1. Common snapping turtles presumably bitten by alligator snapping turtle, Montgomery County, Kansas. Carapace length = 155 mm straight-line maximum, postmortem weight = 670 g (top). Carapace length = 178 mm straight-line maximum, postmortem weight = 975 g (bottom).

Alligator snapping turtles in captivity have been observed to stalk and eat live turtles of the genera *Deirochelys*, *Kinosternon*, *Graptemys*, *Chrysemys*, and *Chelydra* (Allen and Neill 1950. Spec. Publ. No. 4, Ross Allen's Reptile Institute; Ernst and Barbour 1989. Turtles of the United States. Smithsonian Inst. Press, Washington, D.C. 313 pp.; Pritchard 1989. The Alligator Snapping Turtle: Biology and Conservation. Milwaukee Publ. Mus., Milwaukee, Wisconsin. 104 pp.). Our observation is the first such interaction noted in the field. Ernst and Barbour (*op. cit.*) reported that *M. temminckii* does not occupy the same habitat as *C. serpentina*, but prefers a more sedentary existence in deeper waters. Our

observations of its interaction with *C. serpentina* cast doubt on the universality of this claim. Further, we captured six *C. serpentina* in turtle traps set in areas used by the alligator snapping turtle in Onion Creek.

It is impossible to determine if our observations represent predation attempts or agonistic territorial behavior. Our observations suggest *M. temminckii* and *C. serpentina* may utilize similar habitats on occasion.

These observations were made possible in part by the Kansas Department of Wildlife and Parks' Kansas Nongame Wildlife Improvement Fund (Chickadee Checkoff) and Emporia State University via a Faculty Research and Creativity Grant.

Submitted by **PAUL A. SHIPMAN, DAVID R. EDDS**, Division of Biological Sciences, Box 4050, Emporia State University, Emporia, Kansas 66801, USA, and **DOUG BLEX**, Elk City State Park, Kansas Department of Wildlife and Parks, P.O. Box 945, Independence, Kansas 67301, USA.

PLATEMYS SPIXI (Grooved Sideneck Turtle). **PARASITISM.** During a study of aquatic reptiles in a reservoir in the region of Américo Brasiliense, São Paulo, southeastern Brazil (21°45'S, 48°08'W), we collected two female and one male *Platemys spixi* (female #1: CLC = 192 mm; PL = 153 mm; W = 620 g; female #2: CLC = 190 mm; PL = 156 mm; W = 650 g; male #1: CLC = 157 mm; PL = 119 mm; W = 325 g). Numerous leeches of the family Hirudidae (probably *Glossiphonia*) were found on the turtles (female #1 had 244 leeches; female #2 and male #1 only 26 each). The leeches were concentrated in the skin folds on the axillary and inguinal regions of the turtles. Leeches on female #1 spread evenly over the surface of the carapace after a period of exposure to sunlight and warming.

All leeches on female #1 were removed, and the turtle was returned to the reservoir for 24 h, after which we found 11 new leeches on the turtle s inguinal region. Afterward, female #1 was kept in captivity for six months. During this period, the leeches remained on the turtle.

Leeches have been reported on *Kinosternon sonoriense*, but were observed only on the carapace (Hulse 1976. J. Herpetol. 10:45–48). In *P. spixi* the leeches occur in the inguinal and axillary regions, probably because the folds of these regions are protected by the carapace, providing the leeches with highly vascularized tissues for feeding.

We are grateful to Nelson da S Cordeiro for identification of the leeches, to Aricio Xavier Linhares, Ivan Sazima, Johannes Kempers, Karin D. Kempers, Keith S. Brown, and Randy D. Jennings for reading and making suggestions to the manuscript and to the "Clube Nautico Araraquara" for supporting the study on aquatic reptiles.

PSEUDEMYS CONCINNA (Cooter). **MAXIMUM SIZE.** Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.) give maximum sizes for several races of *Pseudemys concinna*, showing a maximum of 17 1/4 in. (438 mm) (straight-line carapacial length; CL) for *P. c. suwanniensis* but no more than 14 3/4 in. (375 mm) for any other race. An extensive area of intergradation involving *P. c. concinna*, *P. c. suwanniensis*, *P. c. hieroglyphica*, and *P. c. metteri* was depicted by Ward (1984. Spec. Publ. Mus. Texas Tech. Univ. [21]:1–50); Conant and Collins (*op. cit.*) show a gap belween the range of *P. c. suwanniensis* and the intergrade area and other races. From that intergradation zone the Tulane University Museum of Natural History collection contains TUMNH 29861, a female measuring 15 1/8 in. (383 mm) CL collected from Gulf County, Florida, 4 mi. N of Wewahitchka at the bridge by the Chipola Dam on the Chipola River (forming Dead Lake) by Joseph T. Willis and Felix Famularo on 10 June 1963. Another specimen, TUMNH 29861, also a female measuring 383 mm CL, was collected in Gulf Co., Florida, 3 mi. E of Wewahitchka in the Chipola River on 12 June 1966 by a Tulane University environmental biology class led by R. D. Suttkus. Whatever genetic or environmental influences that have resulted in *P.c suwanniensis* reaching substantially larger size than the other races of *P. concinna* apparently persist in the intergradation zone.

PSEUDEMYS TEXANA (Texas River Cooter). **NESTING INTERFERENCE**. The exotic red fire ant, *Solenopsis invicta*, has been reported to have an adverse affect on both invertebrates (Porter 1990. Ecology 71:2095–2106) and vertebrates (Mount et al. 1981. J. Alabama Acad. Sci. 52:71–78). In the case of turtles, Mount et al. (*op. cit.*) report several instances of hatchling turtle mortality due to fire ants; however, fire ants have not been reported to interfere with adult turtles during nest construction.

During a herpetofaunal survey of Camp Mabry in Austin, Texas (11 June 1993), a *Pseudemys texana* was discovered in the initial stages of nest excavation. The turtle was discovered at ca. 1115 h, and probably had been digging for less than 1 h. At that time the turtle was covered with ca. 150-200 fire ants. These ants were probably from two colonies located about 3 m away. Observer interference was kept to a minimum by periodically checking the turtle from a distance using binoculars. After 45 min the turtle ceased nest excavation, and returned to the nearest pond ca. 100 m away. The irritation caused by the fire ants presumably prevented the *P. texana* from completing the nesting process.

LACERTILIA

CALOTES VERSICOLOR (Oriental Garden Lizard). **CANNIBALISM and DIET**. Cannibalism or intraspecific predation refers to the killing and consumption of an individual of the same species at any stage of its life cycle. This behavior occurs in over 1000 species of animals (Polis 1981. Ann. Rev. Ecol. Syst. 12:225–251; Elgar and Crespi 1992. Cannibalism: Ecology and Evolution Among Diverse Taxa). In reptiles, cannibalism has been observed in both captive (Frye 1991. Biomedical and Surgical Aspects of Captive Reptile Husbandry, Vol. 1:67) and wild populations (Fox 1975. Ann. Rev. Ecol. Syst. 6:87–106; Rocha 1992. Herpetol. Rev. 23(2):60; Rootes and Chabreck 1993. Herpetologica 49(1):99–107) and may involve adults cannibalizing juveniles or subadults, adults cannibalizing eggs, and juveniles cannibalizing juveniles in a descending order of size (Polis and Myer 1985. J. Herpetol. 19:99–107).

During a study on food habits and gastrointestinal parasites of *Calotes versicolor* in 1992, I examined stomach contents of 124 adult lizards (SVL 74-122 mm) collected from two urban parks in Singapore (1°09'N, 103°38'E; 1°29'N, 104°06'E) and found two

positive cases of cannibalism. The stomach of one lizard (SVL 104 mm, TL 342 mm, mass = 38.92 g), collected on 12 August 1992, had one slightly digested conspecific juvenile of SVL 35 mm, ants, beetle larva, and plant materials, while that of the other cannibalistic lizard (SVL 110 mm, TL 394 mm, mass = 44.15 g), collected on 18 September 1992, contained an undigested conspecific juvenile of SVL 41 mm, a cockroach, beetles, and ants. In both cases, the juvenile lizards were swallowed whole, easily identifiable, and had only a few teeth marks on the midbody skin. The orientation of the preys' head in the distal end of the predators' stomachs indicates that the juvenile conspecifics were eaten head first.

Calotes versicolor feeds primarily on insects, but adults occasionally prey on small birds, nestlings, frogs, and geckos (Rao 1975. British. J. Herpetol. 5(4):467–470; Sharma 1989. J. Bombay Nat. Hist. Soc. 88:459). The first record of intraspecific predation in *C. versicolor* was an anecdotal report of a sighting of an adult lizard (TL 330 mm, sex unknown) attacking and swallowing a subadult conspecific (Sharma 1991. J. Bombay Nat. Hist. Soc 88(2):290–291). The findings of conspecific individuals in the stomach contents, a first record for the species, confirms cannibalistic behavior in this species. The low incidence (1.6%) of cannibalism indicates that intraspecific predation is incidental and probably represents opportunistic carnivory. *Calotes versicolor* is sexually dimorphic; males are larger than females. The observation that both cannibalistic lizards were males further supports the hypothesis that sexual differences in frequency of cannibalism could be related to the larger size of males (Rocha, *op. cit.*) The study was supported by a research grant SIBiol RP10/92 from the Singapore Institute of Biology.

Submitted by **C. H. DIONG**, Division of Biology, School of Science, Nanyang Technological University, National Institute of Education, 469 Bukit Timah Road, Singapore 1025.

CTENOSAURA PECTINATA (Mexican Spiny-tailed Iguana). **PREDATION**. Ramirez-Bautista and Uribe (1992. Herpetol. Rev. 23:82) reported ingestion of *C. pectinata* by the snake *Trimorphodon biscutatus* in Jalisco, México. Here we report predation on this species by another snake, *Boa constrictor imperator*.

On 3 July 1993 while collecting in a tropical deciduous forest near Km 186 (México Highway 95, México-Acapulco) at 650 m elevation, we observed a *B. constrictor imperator* to fall from an *Acacia* sp. tree (2 m high). The snake was constricting a female *Ctenosaura pectinata* that had some acacia leaves in its mouth. The snake constricted the lizard at its abdominal region and was biting the lizard's right shoulder. The snake took 15 min to kill the lizard after which we collected it to prevent ingestion. The lizard (JLE00240) measured 340 mm in SVL and 1030 mm in total length. The snake measured 1600 mm total length. We released the snake at the site of capture. This is the first record of predation on *C. pectinata* by *Boa constrictor*.

We thank Susana Sanoja-Sarabia for field assistance.

EUMECES LONGIROSTRIS (Bermuda Rock Lizard or Skink) **PREDATION**. On 5 August 1993, on Castle Island, Bermuda, we observed an adult male of the introduced Jamaican anole, *Anolis grahami* (SVL ca. 70 mm), consuming a recent hatchling of *Eumeces longirostris*, estimated SVL ca. 30-35 mm. The anole was on top of a stone wall, swallowing the skink head first, with the jaws of the anole at the level of the anterior limbs of the skink. After 2-3 minutes, the previously immobile skink writhed weakly, and was then ingested further. After the skink had been consumed to the level of the hind limbs (with feet and tail base protruding from the mouth of the anole), the anole ran from the top of the wall and was lost from view. The tail of the skink had been autotomized prior to our observations and was not found after the anole departed.

This is the first observation of reptile predation upon *E. longirostris*. It is also the first record of *Anolis* eating a skink. *Anolis grahami* is known to consume other anoles, but its diet in Bermuda consists primarily of hemipteran and hymenopteran insects (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville, 720 pp.).

Anolis grahami was introduced to Bermuda from Jamaica in 1905 (Wingate 1966. Herpetologica 21:202–218). It occurs throughout Bermuda, and almost completely overlaps the range of *E. longirostris*, which is the only terrestrial vertebrate native to Bermuda, and which remains common only in a few localities, notably on the islands of Castle Harbour. Hatchling skinks appear in late July to mid-August, and even if they are uncommon prey items of *A. grahami*, predation by the anole may be a serious threat to this declining species, which is also killed by feral and domestic cats, introduced kiskadee flycatchers (Aves: Tyrannidae: *Pitangus sulphuratus*), and recently reintroduced yellow-crowned night-herons (*Nyctanassa violacea*) (Wingate, pers. obs.). A larger introduced species of *Anolis* (*A. leachi*) is well-established in Bermuda and could also be considered as a potential predator of *E. longirostris*.

GAMBELIA SILA (Bluntnose Leopard Lizard). **CANNIBALISM**. *Gambelia sila* is a large predacious lizard of the San Joaquin Valley in California and often is the most conspicuous and behaviorally dominant local lizard species. Its chief prey by number are insects, especially orthopterans, although small lizards can account for a large portion of the mass of their diet (Montanucci 1965. Herpetologica 21:270–283). Adult *G. sila* are twice the length of conspecific hatchlings and weigh ten times more. Although the most common lizard prey are *Uta stansburiana*, *G. sila* are known to eat small conspecifics (Montanucci, *op. cit.*). However, no specific instances of cannibalism have been recorded. Here we report on two observations of adult *G. sila* eating hatchling conspecifics.

On the morning of 4 August 1991, we were censusing one of our plots on the Elkhorn Plain, San Luis Obispo Co., California, used to study the long-term demographics of *G. sila*. While walking the plot, we spotted an adult male (107 mm SVL, 35 g) in the open, about 100 cm from clumps of snakeweed (*Gutierrezia californica*) on a small berm of a dirt road. As we approached, it quickly snatched at the ground as a small lizard ran by. The male caught the small lizard and swallowed it, with only the tail of the captured lizard visible after a few seconds. The tail of the captured lizard extending from the mouth of the adult male was markedly banded, which is a positive identification of a hatchling *G. sila*. Tails of the other two lizards found at this site are either plain brown (*U. stansburiana*) or bright blue (hatchling *Cnemidophorus tigris*).

The second instance of cannibalism was noted on 11 August 1993, and also occurred on the Elkhorn Plain. An adult female *G. sila* (99 mm SVL, 28 g), found during surveying, had the rear legs and tail of a hatchling *G. sila* sticking out of its mouth. We use PIT tags to permanently mark *G. sila* (Germano and Williams 1993. Herpetol. Rev. 24:54–56.), and both lizards had PIT tags. The

hatchling was 53 mm SVL and 4.2 g when first marked 8 August 1993. We kept the female in captivity until it passed the PIT tag of the hatchling, which occurred 15 August 1993.

Peak activity periods of adult and hatchling *G. sila* usually are temporally separated. The greatest activity of yearlings and adults occurs from April to June, and some activity may occur until September (Tollestrup 1982. Am. Midl. Nat. 108:1–20; Germano and Williams, unpubl. data). Yet, only a small percentage of the adult population of *G. sila* remains active past July on the Elkhorn Plain, and this has occurred three times in 6 yr (Germano and Williams, unpubl. data). In contrast, *G. sila* usually hatch in late July or early August and remain active until October or early November (Tollestrup, *op.cit.*; Germano and Williams, unpubl. data). By the time hatchlings emerge from winter torpor the following spring, they are sufficiently large to escape predation by larger conspecifics. This separation of activity periods effectively minimizes impact to the hatchling population by adults, and also makes the observation of cannibalism by researchers unusual.

We thank Walter Tordoff III, Corey Cates, Terry Trasatti, Jr., and Damien Germano for help with censuses when these observations were made.

SCELOPORUS MUCRONATUS MUCRONATUS (NCN). **PREDATION**. This species is distributed in parts of the Mexican states of Veracruz, Hidalgo, México, Tlaxcala, Puebla, and D.F. (Alvarez and Huerta 1973. An. Esc. Nac. Cienc. Biol. Mex. 20:177–184) at high elevations where rocky outcrops or lava deposits provide crevice microhabitats. Natural history observations are limited to reproduction (Mendez-de la Cruz et al. 1988. J. Herpetol. 22:1–12) and diet (Mendez-de la Cruz et al. 1992. Southwest. Nat. 37:349–355).

On 25 July 1993 while collecting reptiles near km 24.5 on the Ajusco-Tianguistenco highway (Mex. Highway 892, D.F.) at an elevation of 3500 m, we collected a female *Barisia imbricata imbricata* (JLE00293, wet mass 10.0 g, SVL 98 mm) that had eaten a young *S. m. mucronatus* (SVL 30 mm). Previously we reported *S. m. mucronatus* to eat young *Barisia* at this site (Lemos-Espinal and Ballinger 1992. Herpetol. Rev. 23:117). This is an interesting and rarely recorded situation where syntopic lizards are mutual predators rather than competitors. Adults of *S. m. mucronatus* were common on basaltic rocks and lava at this site, whereas young were more commonly observed at the edge of basaltic rocks and areas of grass (*Festuca amolisma*) where *B. i. imbricata* was quite common (N = 57 observed). This is the first account of predation on *S. m. mucronatus* by *B. i. imbricata*.

Preserved specimen JLE00293 will be deposited in the Museum of Natural History, University of Kansas. Susana Sanoja-Sarabia kindly provided field assistance.

Submitted by **ROYCE E. BALLINGER**, School of Biological Sciences, University of Nebraska Lincoln, Lincoln, Nebraska 68588, USA, and **JULIO LEMOS-ESPINAL**, Laboratorie de Investigacion en Ecologia, CyMA, UIICSE, ENEP Iztacala, UNAM, Apartado Postal 314, Tlalnepantla, Edo. de Mex., México.

SCELOPORUS SPINOSUS SPINOSUS (NCN). **BEHAVIOR**. On different occasions during a three-year study of cactus wren (*Campylorhynchus brunneicapillus*) ecology in the southwestern United States and México, one of us (GHF) observed reptiles (including an unidentified colubrid snake and an unidentified iguanid lizard) using unoccupied nests of this bird species as diurnal refugia. The nests are large (average 19.5 cm x 16.0 cm), thick-walled, enclosed structures made primarily of grass, and frequently are maintained and used year-round as nighttime roosts. Nests are typically placed in hard-to-reach locations in spinescent vegetation. On 2 July 1991 (ca. 1530 h) in eastern Guanajuato, México, GHF observed a *Sceloporus spinosus spinosus* in a cactus wren nest located 1.5 m above ground in a 1.8-m tall cholla cactus (*Opuntia* sp.), in a sandy wash with scattered cholla, prickly pear (*Opuntia* sp.), and columnar cacti (*Cereus* sp.). The lizard, estimated to be ca. 120 mm SVL, was completely concealed inside the nest and was not collected. There was no precipitation falling at the time of this observation, but the surrounding area had received frequent rain for several weeks. Portions of the study site were flooded, and slowly moving water was observed in areas that were dry during March 1991. These observations indicate that reptile species use the arboreal nests of the cactus wren for shelter. *S. spinosus spinosus* evidently uses these nests as refugia during flooding, and nests may also provide suitable microclimates and potentially allow for predator avoidance at other times.

We thank Hobart M. Smith for encouraging us to publish this record and for identifying the *S. spinosus spinosus* from a photograph.

Submitted by **GREG H. FARLEY** and **JAMES N. STUART**, Department of Biology and Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

SCELOPORUS UNDULATUS CONSOBRINUS (Southern Prairie Lizard). **PREDATION**. On 27 July 1992, while conducting a survey of lizards of the genus *Sceloporus*, we collected an adult male *S. undulatus consobrinus* (MZFC 5337-3, 53.9 mm SVL, 121 mm TL) on a Joshua tree (*Yucca* sp.) in xerophytic habitat, 1 km SE Castaños, near Monclova, Coahuila, México, elevation 969 m. Examination of the stomach contents revealed a small portion of indeterminable material, and the head and neck of a hatchling *Cnemidophorus inornatus*, 4.6 mm head width, with the color pattern typical for this species. The anterior dorsal portion of head, which was ingested first, was crushed from snout to interparietal area, and did not show scales or skin.

Smith (1946. Handbook of Lizards. Comstock Publishing Associates, Ithaca, New York. 557 pp.) reported that *S. u. consobrinus* consumed beetles, ants, grasshoppers, and fragments of vegetable matter. Groves (1971. J. Herpetol. 5(3-4):205) reported cannibalism and predation on other non-sceloporine lizards by *S. undulatus hyacinthinus*.

Predation on teiid lizards by sceloporines was reported by Vitt and Ohmart (1974. Herpetologica 30(4):413); who found that *S. magister* preyed on juvenile *C. tigris*.

Ferguson et al. (1983. *In* R. B. Huey et al. (eds), Lizard Ecology, Studies of a Model Organism, pp. 134–148. Harvard Univ. Press., Cambridge, Massachusetts) suggested that in *S. u. garmani* aggressive behavior is due to reproductive activity associated with territoriality. We think this phenomenon is also likely for the case reported here, as the enlarged testes of the *S. u. consobrinus* suggested it was sexually active.

We thank Hobart Smith and Oscar Flores for reviewing this paper. This work was funded by a grant (NSF-INT DEB911909) to Jack W. Sites, Jr. and to Dirección General de Apoyo al Personal Académico (DGAPA) project IN201789.

SERPENTES

ALSOPHIS VUDII VUDII (Brown Runner). **DIET and GROWTH**. An adult female (84.0 cm SVL, 116.7 cm TL, 196.0 g [mass minus prey item]) was caught on 14 July 1993 on the ESE side of Raleigh Beach on the north end of Waderick Wells Cay, Exuma Cays Land and Sea Park, Exuma Islands, Bahamas. This snake exceeds the maximum SVL (76.5 cm) reported by Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville, xvi + 720 pp). The snake showed an obvious body bulge indicating it had fed recently. The prey, which we palped from the body, was a large male *Ameiva auberi* (10.5 cm SVL, 34.4 cm TL, 34.5 g). The lizard had been ingested head first and showed no signs of digestion. It represented 29% and 18%, respectively, of the total length and weight of the snake. The snake was collected at 1655 h (EST) as it moved from a sandy beach dominated by palms where *Ameiva* lizards were plentiful to an adjoining limestone ridge with coppice vegetation. The *Alsophis* (marked #124 by scale clipping) was originally captured on 17 March 1992 in a palm thicket on the NE side of Powerful Beach, approximately 185 m from the recapture site. Between captures (484 days), the snake increased 1.5 cm in SVL, 4.2 cm in TL, and 21.0 g in weight. Schwartz and Henderson (*op. cit.*) listed frogs, lizards, snakes, mice, and birds in the diet of this species. They found that *Ameiva* accounted for only 4.1% of the 49 food items identified from *A. vudii*.

Submitted by **RICHARD FRANZ**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, and **C. KENNETH DODD, JR.**, National Ecology Research Center, U.S. Fish and Wildlife Service, 412 N.E. 16th Avenue, Room 250, Gainesville, Florida 32601, USA.

CHIRONIUS BICARINATUS (NCN). **FORAGING BEHAVIOR**. An adult male *Chironius bicarinatus* (preserved SVL 717 mm, TL 414 mm) was observed on 7 May 1982 hunting in *Viresia gigantea, V. saundersii, V. bituminosa,* and *Neoregelia compacta* (all are species of Bromeliaceae) in a garden at São Conrado, Rio de Janeiro, RJ, Brasil, adjacent to the Tijuca Forest National Park. The snake elevated the anterior part of its body and systematically dove into each axil of the bromeliads, until finding a *Scinax trapicheiroi* (Hylidae) that was promptly swallowed. At the same location, another *C. bicarinatus* was observed trying to cross a streamlet to reach a bromeliad. The animal repeatedly attempted to extend its body over the water at several different points, until finding a dry path. It is well known that bromeliads provide habitat for a rather diverse fauna of invertebrates and small vertebrates, especially anurans, and these observations lead us to speculate that *C. bicarinatus* is an active forager of bromeliad-inhabiting anurans. This report also supports Weist's [1978. Revision of the Neotropical Snake Genus *Chironius* Fitzinger (Serpentes, Colubridae). Ph.D. Thesis, Texas A&M University] findings that this species is stenophagous, feeding only on anurans. The first specimen was deposited in the collection of the Biology Institute of the Federal University of Rio de Janeiro (SPCS 86).

Submitted by **SERGIO POTSCH DE CARVALHO-SILVA** and **RONALDO FERNANDES**, Departamento de Zoologia, Instituto de Biologia, Universidade Federal do Rio de Janeiro, Caixa Postal 68044, Cidade Universitária 21944-970, Rio de Janeiro RJ, Brasil.

CROTALUS HORRIDUS (Timber Rattlesnake). **COLORATION**. An essentially striped specimen (Tulane Museum of Natural History TU 28514) was obtained 3 April 1981 on the Tulane University F. Edward Hebert Center located about 5 km NE of Belle Chasse, Plaquemines Parish, Louisiana. A striped specimen from Pennsylvania was described by Gloyd (1934. Pap. Michigan Acad. Sci., Arts Lett. 20:661–668), and Nickerson and Mays (1968. Wasmann J. Biol. 26:125131) reported two striped specimens from close proximity in extreme northern Illinois. Nickerson and Mays included a photograph and a drawing of the skin of one of the Illinois specimens.

The present specimen is a male 109.5 cm SVL plus 8.2 cm to base of rattle. The anterior third of the body shows two abortive chevrons. Otherwise, on either side of the middorsal yellow band a disrupted dark stripe, usually one scale wide, runs along scale rows 3-4 from the middorsal line. Another disrupted dark stripe, 1/2 scale wide, runs on each side along scale rows 5-6 from the ventral scutes. Between each of the lower disrupted stripes a dark blotch reaching to the 4th scale row above the ventrals is present.

The scale counts of 169 ventrals, 27 single plus one divided subcaudals, 25 rows at midbody, 14-14 supralabials, and 15-17 infralabials fall very close to the averages for southern specimens (often referred to as *Crotalus horridus atricaudatus*) as reported by Klauber (1956. The Rattlesnakes. University of California Press, Berkeley and Los Angeles. 2 vols.).

The present specimen demonstrates that a striped mutation can occur at widely disparate parts of the range.

Submitted by **HAROLD A. DUNDEE**, Department of EEO Biology, Tulane University, New Orleans, Louisiana 70118-5698, USA.

MASTICOPHIS FLAGELLUM (Western Coachwhip). **FORAGING BEHAVIOR**. Intrasubordinal predation is not uncommon in snakes. Kingsnakes (*Lampropeltis* spp.), coral snakes (*Micrurus* spp.), and indigo snakes (*Drymarchon*) have long been known to prey on other snakes (Conant 1958. A Field Guide to Reptiles and Amphibians, Houghton Mifflin Co., Boston Massachusetts. 366 pp.).

On 26 June 1991, approximately 3 km W of Barstow on State Hwy 247, San Bernardino Co., California, we observed an adult *Masticophis flagellum piceus* moving quickly with its head raised approximately 15 cm above the ground and carrying a dead glossy snake (*Arizona elegans*) in its mouth. Upon our approach the *Masticophis* dropped the snake and retreated. The glossy snake was dorso-ventrally flattened apparently as a result of being run over by an automobile. After we retreated several meters, the *M. flagellum* immediately returned to the glossy snake, retrieved it, and continued on its way.

Cowles (1946. Herpetologica 3:121–122) reported carrion-eating behavior (a bird carcass) by *M. flagellum* in Riverside Co., California. Our observation documents a second incidence of carrion consumption by *M. flagellum*. To our knowledge, this is the first observation of *M. flagellum* using snake carrion and exploiting a "road kill" as a food source.

Submitted by **MICHAEL F. SMALL, STEPHEN P. TABOR,** and **CHRIS FAZZARI**, BioEnvironmental Associates, 4209 Lantados Street (Suite A), Bakersfield, California 93307, USA.

NERODIA RHOMBIFER RHOMBIFER (Diamondback Water Snake). **REPRODUCTION**. *Nerodia rhombifer* reaches the northern limit of its range in central Illinois (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.; Smith 1961. The Amphibians and Reptiles of Illinois. Illinois. Nat. Hist. Surv. Bull. 28:1–298), where it is restricted to habitats bordering the Illinois and Mississippi Rivers (Smith, *op. cit.*).

We collected two gravid females from Calhoun Co., Illinois, on 26 July 1992. One female, found dead from unknown causes, contained 34 embryos (INHS 10911, female and embryos). A second female was caught on 29 July 1992, near the location where the dead female had been found. This animal was kept in an aquarium and fed living centrarchid fishes until the birth of the litter on 16 September 1992.

The second female had 40 offspring; all were born alive and emerged from fetal membranes unassisted. Eighteen were males and 22 were females, making a male to female ratio of 0.82, not statistically distinguishable from unity ($X^2 = 0.40$, $p > 0.05$). Birth began at about 1900 h and was completed by 2300 h. Mass, snout-vent length (SVL), and total tail length (TTL) of the female and young were measured. Neonates were weighed (nearest 0.01 g) and measured (nearest mm) between 0400 and 0600 h on 17 September. Gender of the neonatal snakes was determined by the method described by Gregory (1983. Herpetol. Rev. 14:42–43). The female was also weighed (to the nearest 1 g) and measured (to the nearest mm) on 17 September. The adult female weighed 625 g and measured 900 mm SVL and 100 mm TTL. The female and all young were released on 21 September 1992.

We estimated relative clutch mass (RCM) by dividing offspring mass by the sum of the female mass after parturition plus the offspring mass (Seigel and Fitch 1984. Oecologia (Berlin) 61:293–301; 1985. J. Anim. Ecol. 54:497–505; Seigel et al. 1986. Herpetologica 42(2):179–185). The estimate therefore does not include the mass attributable to birth fluids and embryo membranes. We calculated a RCM of 0.370.

The mean mass of neonates was 9.14 g for males (range = 8.29–9.80 g; SD = 0.43) and 9.19 g for females (range = 7.99–9.76 g; SD = 0.44). The means do not differ significantly ($t = -0.349$, $p > 0.05$).

Mean SVL for males was 211.2 mm (range = 200–220 mm, SD = 5.77), and mean TTL males was 72.6 mm (range = 66–80 mm, SD = 3.52). Mean SVL for females was 213.2 mm (range = 203–225 mm, SD = 5.45), and the mean TTL for females was 66.3 mm (range = 58–71 mm, SD = 3.43). SVL did not differ significantly between male and female neonates ($t = -1.0977$, $p > 0.05$). However, TTL was significantly shorter for females than males ($t = 5.498$, $p < 0.0001$).

Little is known about reproduction of *N. rhombifer* in Illinois. Smith (*op. cit.*) reported litters of 23 and 32 from specimens collected in Illinois. Anderson (1965. The Reptiles of Missouri. University of Missouri Press, Columbia, Missouri, xxiii + 330 pp.) reported mean litter size of 47.3 (N = 22) based on dissection of gravid females and on counts of live-born litters from Missouri. In Indiana, Minton (1972. Amphibians and Reptiles of Indiana. Ind. Acad. Sci. Monogr. 3:1–346) documented 15 embryos from a single gravid specimen.

There are no previous reports of measurements of lengths and weights of entire litters of this species. In their review, Seigel and Fitch (*op. cit.*) found no published reports of RCM for *N. rhombifer* but they used unpublished data to calculate an RCM of 0.289 for the species. We observed a much higher value (0.370) in the single litter for which it could be measured. Compared to RCM values reported for other natricines, the RCM that we determined for *N. rhombifer* is closer to that reported by Seigel and Fitch for *Clonophis kirtlandii* (0.396 from Conant 1943. Am. Midl. Nat. 29(2):313–341; 0.386 from Tucker 1976. J. Herpetol. 10(1):53–54); we determined a somewhat lower RCM value (0.337) for *C. kirtlandii* based on data reported by Powell and Parmerlee (1991. Bull. Chicago Herpetol. Soc. 26(2):32). The large range in RCMs for natricines suggests that many more data are needed before natural variability in this important life history trait can be adequately described.

We thank Mack Sitzes for assistance in capturing the female. John Nelson helped with statistics. Charles Theiling also assisted with statistical evaluations of the data. John P. Ballenot, Carie Nixon, Eric Ratcliff, Chuck Theiling, and Glendy Vanderah made comments on the manuscript. Lee A. Fitzgerald made several helpful suggestions on the manuscript.

Submitted by **JOHN K. TUCKER** and **JAMES B. CAMERER**, Illinois Natural History Survey, Long Term Resource Monitoring Program Pool 26, 1005 Edwardsville Road, Wood River, Illinois 62095, USA.

NERODIA SIPEDON (Northern Water Snake). **FATALITY**. Plastic debris has been implicated in the deaths of numerous aquatic and marine vertebrates, including fish, birds, mammals, and turtles (e.g., Committee on Sea Turtle Conservation 1990. Decline of the Sea Turtles: Causes and Prevention. National Academy Press, Washington, DC, 259 pp.). Here we report on mortality to *Nerodia sipedon* caused by entanglement in Bird-X™, a flexible plastic netting used to control bird damage in gardens and orchards.

On 22 June 1992, a female *Nerodia sipedon* (Denison University Vertebrate Collection A0063: 718 mm SVL, 941 mm TL) was found dead, entangled in Bird-X™ used to exclude small rodents from a plant ecology experiment in progress at Mountain Lake Biological Station (MLBS), Giles County, Virginia. The snake had lacerations to the upper thoracic region and prominent constrictions to the mid-tracheal and anterior lung region. Apparently the snake either strangled or perished from thermal stress, as it had been restrained in full sunlight on a warm afternoon. On 17 August 1993, another female *N. sipedon* (DUVC A0075: 595 mm SVL, 771 mm TL) was found entrapped in a snarl of Bird-X™ (a 170 mm fragment discarded from the above experiment), grass, and sedge. It was writhing upside-down when encountered, and the netting had already inflicted multiple lacerations, including an upper-thoracic wound that almost completely severed the ventral and lateral musculature. The wounds were too severe to treat, so the snake was euthanized.

At least three additional snakes were ensnared in plastic netting from 1991-1993 at MLBS, including another *N. sipedon*, a black rat snake (*Elaphe obsoleta*), and a timber rattlesnake (*Crotalus horridus*). The two nonvenomous snakes were released unharmed, but the rattlesnake was already dead when it was discovered. Large, heavy-bodied snakes appear particularly vulnerable to entrapment because their scales snag the flexible netting when they reverse direction. Smaller snakes probably encounter plastic netting frequently but are able to maneuver through the mesh easily. Because they are active hunters that forage along ecotones where trash often accumulates, water snakes appear particularly vulnerable to such accidental fatalities (e.g., Herrington 1985. Herpetol. Rev. 16(4):113).

Submitted by **JOHN E. FAUTH** and **STEPHANIE M. WELTER**, Department of Biology, Denison University, Granville, Ohio 43023, USA.

STORERIA OCCIPITOMACULATA OCCIPITOMACULATA (Northern Red-bellied Snake). **PREDATION**. On 1 July 1992, a 25 cm *Storeria occipitomaculata occipitomaculata* (sex unknown) was found in an American kestrel (*Falco sparverius*) nest box located on a 50% dead tree in the middle of a fallow field on Ile Perrot, Quebec (lat. 45°22'30"N, long. 73°55'00"W). The snake's spinal cord was severed at the base of the head and it was presumed it would soon become food for the three 3-week old *F. sparverius* chicks within the box. According to Sherrod (1978. Raptor Research 12(3/4):49–121), *S. occipitomaculata* has not been recorded previously in the diet of *F. sparverius*. *Falco sparverius* feeds on a variety of reptiles and amphibians, but it is unusual to find *S. occipitomaculata* in the diet due to this snake's habit of residing

under logs, stones, or other cover during most of the day (Froom 1972. The Snakes of Canada, McClelland and Stewart Ltd., Toronto.).

Submitted by **GLENN C. BARRETT***, and **MORRIS R. VILLARROUL,** Avian Science and Conservation Centre, Macdonald Campus, McGill University, 21111 Lakeshore, Ste-Anne-de-Bellevue, Quebec, Canada, H9X 3V9.

* Present address for GCB: 2429 Lakeshore Road, Burlington, Ontario, Canada, L7R.

THAMNOPHIS SIRTALIS SIRTALIS (Eastern Garter Snake). **ALBINISM.** Reports of albinistic and leucistic individuals of this species are not uncommon. Dyrkacz (1981. SSAR Herpetol. Circ. 11) reported 11 instances from throughout its range. However, no reports of albinistic *T. sirtalis* from Virginia have been published (Mitchell, *in press*. The Reptiles of Virginia. Smithsonian Inst. Press, Washington, D.C.). A leucistic, approximately 600 mm total length, adult female *T. s. sirtalis* was found on 2 July 1992 near a small stream on the Clifton Farm, 7 km north of Warrenton, Fauquier County, Virginia. The snake's eyes were normally pigmented, but the skin was uniformly white with only the barest traces of pattern visible (Fig. 1).

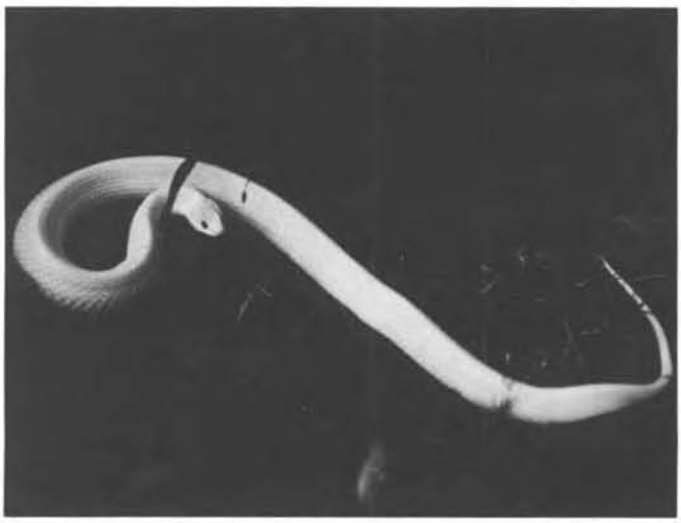

FIG. 1. Leucistic *Thamnophis s. sirtalis* from Fauquier Co., Virginia.

The snake was kept in captivity where it refused food (ranid frogs). On 19 September, it gave birth to 30 neonates, all of which were normally pigmented and patterned. Five of the neonates were either stillborn or died shortly after birth. The female and surviving young were released on 21 September. However, on the following day the female was found at the release site weak and emaciated, and was recaptured. She died on 30 September after regurgitating a force-fed frog. Dissection of the snake revealed one additional, somewhat decomposed neonate, also normally pigmented and patterned. The lack of leucistic neonates in this female suggests that albinism in this species may follow Mendelian inheritance patterns.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19:1–41), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985(3):802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to the Section Co-editors, Joseph T. Collins (USA & Canadian records only), Museum of Natural History—Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA, or Jerry D. Johnson (the rest of the world), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Painter, C. W., and C. M. Milensky. 1993. Geographic Distribution. *Crotalus tigris*. Herpetol. Rev. 24:155-156.

CAUDATA

AMBYSTOMA MACULATUM (Spotted Salamander). USA: TENNESSEE: Humphrys Co: adjacent small creek near jct. Bodine Loop and Cuba Landing Roads. 28 March 1993. M. Varner and B. T. Miller. Middle Tennessee State University (MTSU 84C–85C). Verified by B. T. Miller. New county record (Redmond 1985, A Biogeographic Study of Amphibians in Tennessee, Doctoral Thesis, Univ. Tennessee, Knoxville. 290 pp.).

Submitted by **MURLIN E. VARNER, JR.**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

AMBYSTOMA OPACUM (Marbled Salamander). USA: ILLINOIS: Shelby Co: 2 km W Towerhill & 4 km S Rt. 16 (39°20'53"N, 88°59'30"W). 10 April 1993. Tony Glick. Verified by Ronald A. Brandon. Southern Illinois University at Carbondale (SIUC H-

4451). New county record; extends range ca. 55 km WNW of nearest known locality in Cumberland County (Smith 1961, The Amphibians and Reptiles of Illinois, Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **ALLAN K. WILSON**, Max McGraw Wildlife Foundation, P.O. Box 9, East Dundee, Illinois 60118, USA.

ANEIDES AENEUS (Green Salamander). USA: INDIANA: Crawford Co: see below. 24 August 1993. R. F. Madej. Verified by A. R. Resetar. FMNH 251486. Adult female. This is the first occurence for Indiana. Frozen tissue samples are also stored at the Field Museum of Natural History. Other individuals (adult and juvenile) observed and photographed at site. Precise locality data have been withheld because this species has been recommended for legal protection under the Indiana Nongame and Endangered Species Conservation Act (IC 14-2-8.5).

Submitted by **ROBERT F. MADEJ**, Indiana Department of Natural Resources, Division of Fish and Wildlife, Nongame and Endangered Wildlife Program, 300 West First Street, Bloomington, Indiana 47403, USA.

CRYPTOBRANCHUS ALLEGANIENSIS (Hellbender). USA: ILLINOIS: White Co: Wabash River at Maunie. 8 August 1990. Captured by commercial fishermen, obtained by a fish market in McLeansboro, and given to Saint Louis Zoo where it was displayed until it died in 1993. The frozen specimen was given to the Southern Illinois University at Carbondale Department of Zoology where it was preserved and deposited (SIUC H-4462). Verified by Ron Goellner. Previously considered extirpated from state but, on the basis of this specimen, the Department of Conservation is adding the Hellbender to the list of Illinois endangered species. The most recently documented specimens were from Cave In Rock, Hardin County (1956) and Metropolis, Massac County (1956), both from the Ohio River (Stein and Smith 1959, Copeia 1959:178–179). These specimens, previously reported to be at Southern Illinois University, are now INHS 9669 and 9670, respectively. Stein and Smith (*op. cit.*) mentioned a specimen collected in 1947 near Maunie. Klimstra and Hutchison (1965, Trans. Illinois St. Acad. Sci. 58:151–156) reported a specimen from the Ohio River near Joppa, Massac County, but it is undocumented.

Submitted by **RONALD A. BRANDON**, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA, and **SCOTT R. BALLARD**, Illinois Department of Conservation, Division of Natural Heritage, 4521 Alton Commerce Parkway, Alton, Illinois 62002, USA.

DICAMPTODON TENEBROSUS (Pacific Giant Salamander). USA: WASHINGTON: Pacific Co: tributary of Willapa River, ca. 1.6 km E of Willapa Harbor Airport, NW 1/4 Sec. 15, T14N, R9W. 5 September 1993. W. P. Leonard and D. Doherty. Verified by R. A. Nussbaum. University of Michigan Museum of Zoology, Ann Arbor, Michigan (RAN 31885). First coastal record N of the Willapa River. Extends range ca. 24 km N of only other county record (Jones and Atkinson 1989, Northwest. Nat. 70:40–42.).

Submitted by **WILLIAM P. LEONARD**, Washington Department of Ecology, P. O. Box 47600, Olympia, Washington 98504-7600, USA, and **DEIRDRE DOHERTY**, P. O. Box 319, Bridgeton, New Jersey 08302, USA.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: ALABAMA: Mobile Co: Dauphin Island, Gorgas Swamp. 12 November 1993. T. A. Sinclair. Verified by James D. Lazell. MCZ A11825. New island record; extends range in Alabama W of the Alabama River ca. 117 km S of Greene County locality and ca. 35 km S of Mobile County literature record (Mount 1975, The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.). Salamanders are absent or rare on barrier islands. This increases to three the number found on Dauphin Island (Mount, *op. cit.*).

Submitted by **THOMAS A. SINCLAIR**, The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835, USA.

PLETHODON WEHRLEI (Wehrle's Salamander). USA: NORTH CAROLINA: Alleghany Co: 6.8 km and 6.9 km SSE Edmonds, Saddle Mountain. 14 November 1993. J. C. Beane, J. R. Everhart, and A. B. Somers. NCSM 34832–34833; Surry Co: 5.8 km WSW Low Gap, Saddle Mountain. 16 October 1993. J. C. Beane, C. K. Cheshire, S. K. Eanes, J. R. Everhart, and A. B. Somers. NCSM 34825; 6.0 km WSW Low Gap, Saddle Mountain. 13 November 1993. J. C. Beane and C. K. Chesire. NCSM 34831. All verified by Alvin L. Braswell. A total of eighteen additional specimens from contiguous populations were observed but not collected on 16 October, 22 October, and 13–14 November 1993 at these localities. New county records; second locality for North Carolina. Extends range ca. 70 km S of nearest records in Patrick and Grayson counties, Virginia, and ca. 60 km W of nearest records in Stokes County, North Carolina (Highton 1987, Cat. Amer. Amph. Rept. 402.1–402.3). Only two specimens had been known from North Carolina, and the exact locality and specific collection data for those specimens have apparently not been previously reported. Both are from Hanging Rock State Park in Stokes County. One (NCSM 32093, formerly DU A14806) on 16 April 1978 by J. R. Bailey et al. Highton (1962, Bull. Florida State Mus. 6(3):235–367) noted that Whitetop Mountain in Grayson County, Virginia, was the only site where *P. wehrlei* was sympatric with *P. yonahlossee*. The two species are also sympatric at this new locality.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 29555, Raleigh, North Carolina 27626-0555, USA, and **ANN BERRY SOMERS**, Department of Biology, University of North Carolina at Greensboro, Greensboro, North Carolina 27412-5001, USA.

ANURA

ASCAPHUS TRUEI (Tailed Frog). USA: WASHINGTON: Okanogan Co: Williams Creek (tributary to Twisp River), 0.3 km SW of Twisp River, SW 1/4 Sec. 34, T34N, R19E. 25 September 1993. D. Visalli and W. P. Leonard. Verified by L. L. C. Jones. University of Washington Burke Museum, Seattle, Washington (UWBM 2218). New county record; fills ca. 180 km distributional gap between Chelan County, Washington, and British Columbia along E slope of Cascade Mountains (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. of Idaho Press, Moscow. 332 pp.).

Submitted by **DANA VISALLI**, P. O. Box 175, Winthrop, Washington 98862, USA, and **WILLIAM P. LEONARD**, Washington Department of Ecology, P. O. Box 47600, Olympia, Washington 98504-7600, USA.

ASCAPHUS TRUEI (Tailed Frog). USA: WASHINGTON: Wahkiakum Co: tributary to Elochoman River, ca. 21 km N of Town of Cathlamet, NW 1/4 Sec. 3, T10N, R5W. 29 April 1993. S. W. Manlow. Verified by L. L. C. Jones. University of Washington Burke Museum, Seattle, Washington (UWBM 2216). New county record; extends range ca. 30 km SW in Willapa Hills (Adams 1993, Herpetol. Rev. 24(2): 64). Found in stream with sympatric populations of *Dicamptodon copei*, *D. tenebrosus*, and *Rhyacotriton kezeri*.

Submitted by **STEVEN W. MANLOW**, Washington Department of Wildlife, 11203 NE 96th Street, Vancouver, Washington 98662, USA.

BUFO AMERICANUS (American Toad). USA: ILLINOIS: Fayette Co: Sec. 28, T7N, R3E, junction of Brickyard Branch of South Fork Creek with County Road 2000N, 0.25 km W of St. Elmo. 17 April 1993. J. K. Tucker. Verified by K. Cummings. Illinois Natural History Survey (INHS 10957–10959). Three males. New county record (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298); extends range 24 km S of nearest Illinois record and confirms Smith's hypothesis that species occurs in the county.

Submitted by **JOHN K. TUCKER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 1005 Edwardsville Road, Wood River, Illinois 62095, USA.

BUFO AMERICANUS AMERICANUS (Eastern American Toad). USA: ILLINOIS: Kane Co: 1 km W Rt. 25 and 1.8 km S Rt. 72 (42°5'17"N, 88°15'55"W). 1 September 1993. A. K. Wilson. Verified by Ronald A. Brandon. Southern Illinois University at Carbondale (SIUC H-4473). New county record; Smith (1961, The Amphibians and Reptiles of Illinois, Illinois Nat. Hist. Surv. Bull. 28:1–298) shows literature record but no voucher for the county.

Submitted by **ALLAN K. WILSON**, Max McGraw Wildlife Foundation, P. O. Box 9, East Dundee, Illinois 60118, USA.

BUFO MICROSCAPHUS MICROSCAPHUS (Arizona Toad). USA: ARIZONA: Gila Co: Pinto Creek at U.S. Forest Service Road 287, Sec. 2, T1N, R13E. 19 April 1993. S. G. Seim. Verified by B. K. Sullivan. Arizona State University Lower Vertebrate Collection (ASU 28812). One calling male observed 60 km southwest of nearest record (Sullivan, Great Basin Nat. *in press*). Not previously known to occur on south side of Lake Roosevelt.

Submitted by **SHARON G. SEIM**, Arizona Game and Fish Department, Nongame Branch, 2221 West Greenway Road, Phoenix, Arizona 85023, USA.

BUFO WOODHOUSII FOWLERI (Fowler's Toad). USA: MISSOURI: St. Charles Co: NE 1/4 Sec. 26, T48N, R7E, Ellis Island, Riverlands Road. 2 April 1993. J. Tucker. Verified by L. Page, Illinois Natural History Survey (INHS 10981-10986). Six adults taken AOR. New county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **JOHN K. TUCKER** and **CHARLES H. THEILING**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 1005 Edwardsville Road, Wood River, Illinois 62095, USA.

RANA CATESBEIANA (Bullfrog). USA: ILLINOIS: Peoria Co: Peoria, Teton & N. University Avenue, Sec. 8, T9N, R8E, DOR. 11 July 1993. F. T. Burbrink. Verified by Kevin S. Cummings. Illinois Natural History Survey, Champaign, Illinois (INHS 10973). (Smith 1961, The Amphibians and Reptiles of Illinois, Illinois Nat. Hist. Surv. Bull. 28:1–298) shows a published record but no voucher for this species in the county; new county record.

Submitted by **FRANK T. BURBRINK**, Center for Wildlife Ecology, Illinois Natural History Survey, Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

SCAPHIOPUS HOLBROOKII HURTERII (Hurter's Spadefoot). USA: TEXAS: Grayson Co: 4.8 km SE Denison. 29 April 1993. J. D. Camper. TCWC 70375. Verified by James R. Dixon. County record; fills substantial gap between Denton and Red River counties at western portion of range (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press, College Station, Texas. 434 pp.). Adult taken (2030 h) at breeding pond in lowland area of red-sandy soil about 8 km S Red River.

Submitted by **JEFFREY D. CAMPER**, Department of Biology, Austin College, Sherman, Texas 75091-1177, USA.

SYRRHOPHUS CYSTIGNATHOIDES (Rio Grande Chirping Frog), USA: TEXAS: Tarrant Co: jct. Daggett and Sunset Terrace. 18 September 1993. M. T. Dixon, L. K. Ammerman and L. S. McGown. Verified by James R. Dixon. TCWC 70873–70874. Northernmost record for the species (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press, College Station, Texas. 434 pp.). Introduced into the San Antonio and Houston area via the plant nursery trade, and possibly arrived in Fort Worth in a similar manner. The frogs have established themselves in rocky areas along a two mile stretch on the bluff of the Clear Fork of the Trinity River.

Submitted by **LAURINE S. McGOWN, MICHAEL T. DIXON**, and **LOREN K. AMMERMAN**. Department of Biology, Texas Wesleyan University, 1201 Wesleyan, Fort Worth, Texas 76105, USA.

TESTUDINES

APALONE SPINIFERA ASPERA (Gulf Coast Spiny Softshell). USA: NORTH CAROLINA: Montgomery Co: 5.9 km WSW Pekin in Little River. 20 June 1993. J. C. Beane, S. L. Alford, and J. Hurley. Verified by W. M. Palmer. NCSM color slides JCB 93-1172. New county record (NCSM files).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 29555, Raleigh, North Carolina 27626-0555, USA, and **STANLEY L. ALFORD**, North Carolina Zoological Park, Route 4, Box 83, Asheboro, North Carolina 27203, USA.

CHELYDRA SERPENTINA (Snapping Turtle). USA: ILLINOIS: Kane Co: 1 km W of Rt. 25 & 1.9 km S of Rt. 72 (42°5'15"N, 88°15'56"W). 15 June 1993. L. A. Fray and A. K. Wilson. Verified by Ronald A. Brandon. Southern Illinois University at Carbondale (SIUC R-2500). New county record; (Smith 1961, The Amphibians and Reptiles of Illinois, Illinois Nat. Hist. Surv. Bull. 28:1–298) shows a literature record but no voucher for the county.

Submitted by **ALLAN K. WILSON**, Max McGraw Wildlife Foundation, P. O. Box 9, East Dundee, Illinois 60118, USA.

MELANOCHELYS TRICARINATA (Tricarinate Hill Turtle). INDIA: UTTAR PRADESH: Dehradun: Chandrabani, on Wildlife Institute of India campus. 10 August 1993. Stephen D. Busack. Verified by S. Bhupathy. One live individual, represented by four transparencies (CM Acc. 35560.1–35560.4) and at least ten additional specimens living in the area and individually marked by S. Bhupathy. These turtles may represent a previously unreported and disjunct population 1000 km NW of available records (Tikader and Sharma 1985, Handbook Indian Testudines, Zool. Surv. India, Calcutta, 156 pp.), or an introduction attempt that may be successful.

Submitted by **STEPHEN D. BUSACK**, National Fish and Wildlife Forensic Laboratory, 1490 East Main Street, Ashland, Oregon 97520, USA.

STERNOTHERUS ODORATUS (Common Musk Turtle). USA: MISSOURI: St. Charles Co: NE 1/4 Sec. 26, T48N, R7E, Ellis Island, Riverlands Road. 8 July 1993. J. Tucker. Verified by L. Page, Illinois Natural History Survey (INHS 10987). Adult taken AOR. New county record and second record north of Missouri River for the species (Johnson 1987, The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **JOHN K. TUCKER** and **CHARLES H. THEILING**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 1005 Edwardsville Road, Wood River, Illinois 62095, USA.

TRACHEMYS SCRIPTA (Slider). USA: KANSAS: Riley Co: Fort Riley Military Reservation, Vinton Pond, SE 1/4, NE 1/4 Sec. 35, T10S, R5E. 11 September 1993. J. R. Parmelee. Verified by Joseph T. Collins. KU 221248. Caught in turtle trap; new county record (Collins 1993, Amphibians and Reptiles in Kansas. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Series 13: 1–397).

Submitted by **JEFFREY R. PARMELEE**, Museum of Natural History and Department of Systematics and Ecology, The University of Kansas, Lawrence, Kansas 66045-2454, USA.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: ILLINOIS: Kane Co: Max McGraw Wildlife Foundation, 1.05 km W Rt. 25 & 2.5 km S Rt. 72 (42°4'29"N, 88°16'8"W). 16 July 1993. A. K. Wilson. Verified by R. A. Brandon. Southern Illinois University at Carbondale (SIUC R-2485). Other sightings in area possibly indicate breeding has occurred; new county record (Smith 1961, The Amphibians and Reptiles of Illinois, Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **ALLAN K. WILSON**, Max McGraw Wildlife Foundation, P.O. Box 9, East Dundee, Illinois 60118, USA.

LACERTILIA

ANOLIS SAGREI (Brown Anole). USA: LOUISIANA: East Baton Rouge Parish: Baton Rouge, greenhouse on Sottle Drive, ca. 2 km NE jct. Interstate 10 and Highland Road. 8 October 1993. Mike Leggio. Verified by Richard R. Montanucci. Vertebrate Collection, Department of Biological Sciences, Clemson University (CUSC 792). Single specimen collected. At least five additional individuals observed in greenhouse with *Anolis carolinensis*. Nearest reported populations are in Orleans and Jefferson Parishes, Louisiana (Thomas et al. 1990, Herpetol. Rev. 21:22). Extends range ca. 115 km northeast. Greenhouse may provide thermal refuge from occasional low winter temperatures; it is likely that *A. sagrei* is established at this site. Probably introduced in shipments of houseplants originating from Florida.

Submitted by **STEVEN G. PLATT** and **LANCE W. FONTENOT**, Department of Biological Sciences, Clemson University, Clemson, South Carolina 29634-1903, USA.

CNEMIDOPHORUS DEPPEI DEPPEI (Lagartija Rayada). NICARAGUA: ZELAYA: Puerto Cabezas. 18 May 1970. Jaime D. Villa. KU 174105–8. Verified by Joseph T. Collins; Krukira, ca. 40 km S Puerto Cabezas. 20 December 1991. J. D. Villa, E. J. Petuch, R. Solórzano. Three uncatalogued specimens to be deposited at the University of Florida. First records on the Caribbean versant of Nicaragua, extending distribution beyond the map given by Wright (*In* Wright and Vitt 1993, Biology of Whiptail Lizards [Genus *Cnemidophorus*], pp. 27-81. Publ. Oklahoma Mus. Nat. Hist., Norman, Oklahoma). Extends known range ca. 165 km SSE Tancín, Departamento de Gracias a Dios, the nearest known locality in Honduras (Meyer and Wilson 1973, Los Angeles Co. Mus. Contrib. Sci. 244:1-39), and 320 km NNW of the Ciudad Darío-Sébaco area (Departamento de Matagalpa), the nearest Nicaraguan localities (KU 86066–67, 103270–76). The Tancín specimens (LACM 48023–25, LSUMZ 21628–31), as well as one from Puerto Castillo, Colón (LSUMZ 22482), are also outside the range as depicted in Wright (*op. cit.*).

Submitted by **JAIME D. VILLA**, Department of Biological Sciences, Florida Atlantic University, Boca Raton, Florida 33431-0991, USA.

OPHISAURUS ATTENUATUS (Western Slender Glass Lizard). USA: KANSAS: Saline Co: DOR, 1.5 km SSE Bridgeport, NE 1/4 Sec. 36, T16S, R3W. 21 May 1993. Jerry D. Johnson and Travis J. LaDuc. Verified by Robert G. Webb. University of Texas at El Paso (UTEP 15298). First county record (Collins 1993, Amphibians and Reptiles of Kansas. Third ed. Univ. Kansas Mus. Nat. Hist. Publ. Ed. Ser. 13:1–397.).

Submitted by **JERRY D. JOHNSON**, Biology Department, El Paso Community College, El Paso, Texas 79998-0500 and Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968-0519, USA, and **TRAVIS J. LaDUC**, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas, 19968-0519, USA.

PODARCIS MURALIS (Common Wall Lizard). USA: KENTUCKY: Campbell Co: Ft. Thomas, along Clover Ridge Avenue, 39°05'30"N, 84°27'25"W. 22 September 1993. Matthew and Dana Draud. Verified by Rafe M. Brown. Cincinnati Museum of Natural History (CMNH 3897). State record and collected from a large breeding population. Common across the Ohio River in Cincinnati (Hedeen 1984, Herpetol. Rev. 15:70–71).

Submitted by **MATTHEW DRAUD**, Chandler #17, Behavioral and Evolutionary Sciences, Lehigh University, Bethlehem, Pennsylvania 18018, USA and **JOHN FERNER**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA.

SCINCELLA LATERALIS (Ground Skink). USA: NORTH CAROLINA. Surry Co: 6.5 km NNW Mountain Park along Mitchell River. 11 September 1993. J. C. Beane and A. B. Somers. Verified by W. M. Palmer. NCSM 34711. New county record; extends range ca. 75 km WNW of nearest record in Forsyth County (NCSM files) and partially fills the range hiatus as shown in Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin, Boston, Massachusetts, 450 pp.). Another specimen was observed but not collected 0.8 km SSW Dobson on 3 October 1993.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 29555, Raleigh, North Carolina 27626-0555, USA, and **ANN BERRY SOMERS**, Department of Biology, University of North Carolina at Greensboro, Greensboro, North Carolina 27412-5001, USA.

SERPENTES

CLONOPHIS KIRTLANDII (Kirtland's Snake). USA: OHIO: Greene Co: Belbrook, Spring Lakes. 17 September 1993. Michael Bernhard. Verified by J. T. Collins. Animal photographed and released. KU Color Slide 11044. Adult male found near water during daylight hours. The species is considered threatened in the state of Ohio and is thought to be restricted to a few southern counties. This individual could represent a previously unknown population and is likely the first record of this species in Greene County (Wynne, unpubl. ms.).

Submitted by **GREGORY J. WATKINS-COLWELL**, Department of Biological Sciences, Ohio University, Athens, Ohio 45701, USA.

CROTALUS HORRIDUS (Timber Rattlesnake). USA: LOUISIANA: Beauregard Parish: DOR on U. S. Rt. 190, 5.6 km SW Merryville. 6 October 1972. R. D. Suttkus. Verified by D. A. Rossman. Tulane University Museum of Natural History (TU 28888). New parish record. This is only a short distance (ca. 30 km) from a Newton County, Texas record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M University Press, College Station, Texas. xii + 434 pp.), but equidistant from the two closest localities in Louisiana (111 km west, 111 km south) (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge, Louisiana. xi + 300 pp.). The species is rare in pinelands of Louisiana, occurring

primarily in bottomlands or hardwood forests. The Merryville record is in bottomland forest near the Sabine River.

Submitted by **HAROLD A. DUNDEE**, Department of EEO Biology, Tulane University, New Orleans, Louisiana 70118-5698, USA.

ELAPHE EMORYI (Great Plains Rat Snake). USA: NEBRASKA: Richardson Co: gravel road through center of Sec. 15, T2N, R13E. 31 July 1993. C. Bridgewater and T. Leonard. University of Nebraska at Lincoln (UNL 15399). Verified by John D. Lynch. New county record; easternmost occurrence of the species in Nebraska (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **T. LEONARD**, 5006 South 36th Avenue, Omaha, Nebraska 68107, USA.

NERODIA RHOMBIFER RHOMBIFER (Diamondback Water Snake). USA: ILLINOIS: Calhoun Co: mouth of Swan Lake, Illinois River mile 5.0. 26 July 1992. J. K. Tucker and J. Nelson. Verified by K. S. Cummings. Illinois Natural History Survey (INHS 10911). New county record; extends range 4.9 km SW of nearest Illinois record in Jersey County (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **JOHN K. TUCKER** and **JAMES B. CAMERER**, Illinois Natural History Survey, Long Term Resource Monitoring Program Pool 26, 1005 Edwardsville Road, Wood River, Illinois 62095, USA.

RAMPHOTYPHLOPS BRAMINUS (Braminy Blind Snake). MEXICO: OAXACA: municipality of Cuicatlan, trail station Cuicatlan (17°26'N, 96°13'W), 600 m elev. 28 July 1993. Dan G. Mink. Verified by Oscar Flores-Villela. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de México (MZFC 6009, two specimens). First record for the state and a southwestern range extension of 178 km (airline) from Playa Mocambo, Veracruz, on the Gulf Coast (Mendoza-Quijano et al. 1993, Herpetol. Rev. 24(3):110). Previously reported introductions are in Baja California Sur (Murphy and Ottley 1979, Herpetol. Rev. 10(4):119), Jalisco (Dundee and Flores-Villela 1991, Herpetol. Rev. 22(1):26), Sinaloa, Michoacan, and Guerrero on the Pacific Coast, and inland from Queretaro and Morelos (Dixon and Hendricks 1979, Zool. Verhandelingen 173:1–39).

Submitted by **FERNANDO MENDOZA QUIJANO** and **ALEJANDRA RENDON ROJAS**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de México, Apartado Postal 70-399, México D. F. 04510, México, and **DANIEL G. MINK**, Department of Zoology, Brigham Young University, Provo, Utah 84602, USA.

RAMPHOTYPHLOPS BRAMINUS (Braminy Blind Snake). USA: FLORIDA: Highlands Co: Lake Placid at residence in Placid Lakes subdivision. 26 June 1993. W. E. Meshaka, Jr. Verified by H. R. Mushinsky. Vertebrate collection, Archbold Biological Station (ABS 1177). New county record and northernmost locality in Florida; extends inland range ca. 100 km NW of Palm Beach County record (DeLorey and Mushinsky 1987, Herpetol. Rev. 18(3):56) and ca. 90 km NE of Lee County record (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.). Like *Anolis sagrei* (Godley et al. 1981, Herpetol. Rev. 12(3):84–86), presence of the species on the central ridge is likely the result of introduction of ornamental plants in such human-modified habitats as subdivisions, from which this individual was collected.

Submitted by **WALTER E. MESHAKA, JR.**, Archbold Biological Station, P.O. Box 2057, Lake Placid, Florida 33852, USA.

RHAMPHOTYPHLOPS BRAMINUS (Braminy Blind Snake). USA: LOUISIANA: Orleans Parish: Mid-City area of New Orleans. 11 November 1993. Richard Lopicallo. Verified by Douglas A. Rossman. LSUMZ 56317. New state record (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge. 300 pp). Found under a board on a slab in a city lot that had been used as a storage site for nursery products. Specimen presumably arrived in a potted plant. Other introduced species found in the area are *Eleutherodactylus planirostris*, *Anolis sagrei*, and *Hemidactylus turcicus*.

Submitted by **ROBERT A. THOMAS**, Society for Environmental Education and University of New Orleans, New Orleans, Louisiana 70187-6010.

RHADINAEA FLAVILATA (Pine Woods Snake). USA: ALABAMA: Mobile Co: Mobile, Hillcrest Road near Cottage Hill Road. 23 October 1974. James Harden. University of South Alabama (USA 2163); Scoutshire Woods (Girl Scout Camp), 21.6 km SE Citronelle. 8 May 1982. F. A. Harrington and D. H. Nelson. USA 2306; Mobile, 1255 Dauphin Street. 18 May 1993. J. D. Cochran and C. G. Drew. USA 2409. All specimens verified by Craig Guyer. Substantiates an early literature record from near Mobile (Mount 1975, Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Stat., Auburn, Alabama. 347 pp.). A previous record (USA 1403), also mentioned by Mount (*op. cit.*), was first reported by Jackson and Jackson (1970, Quart. J. Florida Acad. Sci. 33:281–287).

Submitted by **DAVID H. NELSON**, Department of Biology, University of South Alabama, Mobile, Alabama 36688, USA, and **JUSTIN D. COCHRAN**, **CORBERT G. DREW**, and **TERRY D. SCHWANER**, Alabama School of Mathematics and Science, 1255 Dauphin Street, Mobile, Alabama 36604, USA.

RHADINAEA MARCELLAE (NCN). MEXICO: HIDALGO: municipality of Tlanchinol, 5.3 km E Tlanchinol, Arroyo de Apantlazol (21°00'N 98°35'W), 1550 m elev. 28 March 1991. Efraín Hernández García. Verified by Oscar Flores Villela. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de México (MZFC 5868, female). Found crushed on road by potrero surrounded by cloud forest. First record for the state and a southern range extension ca. 60 km SE of nearby record in Xilitla Region, San Luis Potosí (Taylor 1949, Univ. Kansas Sci. Bull. 23(2):169–215); second known specimen of the species. Specimen agrees fully with descriptions of *R. marcellae* (Taylor 1949, *op. cit.* Myers 1974, Bull. Amer. Mus. Nat. Hist. 153(1):88–89) except for the presence of an incomplete neck collar and a high number of ventral scales (137 versus 128 in holotype).

Submitted by **EFRAIN HERNANDEZ GARCIA** and **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de Mexico, Apartado Postal 70-399, D. F. 04510, México.

SALVADORA HEXALEPIS (Western Patchnose Snake). USA: CALIFORNIA: Kern Co: west side of San Joaquin Valley, 6.5 map km NNW McKittrick (T29S, R22E, NW 1/4 of Sec. 19), ca. 152 m elev. 4 May 1992. Scott Cameron. LACM PC 1255 (photo voucher). Verified by R. L. Bezy. The collection site consists of generally flat terrain occasionally dissected by arroyos; the vegetation is saltbush scrub characterized by *Atriplex polycarpa*, *A. spinifera*, and non-native annual grasses. This is the first record of *Salvadora* from the west side of the San Joaquin Valley and bridges a gap in an otherwise enigmatic distribution pattern. *Salvadora* previously has been recorded from the Carrizo Plain to the west (San Luis Obispo County) and from the southeastern margin of the San Joaquin Valley (from near Bakersfield to 2 mi. N of Grapevine Station, Kern County). Despite considerable field work in central California following Bogert's studies of patchnose snakes

(1939, Publ. Univ. California Los Angeles Biol. Sci. 1:177–236; 1945, Amer. Mus. Nov. 1285:1–14), remarkably few specimens have been collected in the southern San Joaquin Valley and adjacent Carrizo Plain, and *S. hexalepis* remains a rare snake at the western margin of its range (Hansen, unpubl.). The San Joaquin Valley population has been referred to the Mojave Desert subspecies *S. h. mojavensis* while specimens from the Carrizo Plain southward belong to the subspecies *S. h. virgultea* (Bogert 1945, *op. cit.*; Stebbins 1985, A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.). Because the present specimen was released after being photographed in the field, we are unable to make any allocation to subspecies. However, its occurrence in the San Joaquin Valley suggests placement within *S. h. mojavensis*; thus, this record extends the range of that subspecies 61 map km W from Bakersfield, Kern County.

Submitted by **SCOTT CAMERON**, Michael Brandman Associates, 7676 Hazard Center Drive, Suite 400, San Diego, California 92108, USA, and **ROBERT W. HANSEN**, 16333 Deer Path Lane, Clovis, California 93611, USA.

STORERIA DEKAYI (Brown Snake). USA: ILLINOIS: Fayette Co: 8.9 km W Rt. 128 on 3050N and 3000N. 7 August 1993. John E. Petzing. Verified by Ronald A. Brandon. Southern Illinois University at Carbondale (R-2484). County record; original specimen was a live female found early June 1993. Gave birth to eleven juveniles on 7 August 1993, two of which died and were used as the voucher specimens. Found on gravel road bordered by hardwood forest on west, pasture on east, and 0.3 km S of Lorton's Bridge (Kaskaskia River).

Submitted by **JOHN E. PETZING**, Rural Route 1, Box 87, Beecher City, Illinois 62414, USA.

STORERIA DEKAYI WRIGHTORUM (Midland Brown Snake). USA: ILLINOIS: Fayette Co: SW 1/4 Sec. 26, T5N, R1W, 8 km WSW Shobonier. 21 November 1993. J. B. Hatcher. Verified by C. Phillips. Illinois Natural History Survey (INHS 11110–11111). Adult male and subadult female found in flooded subimpoundment area of Carlyle Lake. New county record (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **JOHN K. TUCKER, JAMES B. HATCHER**, and **DIRK W. SOERGEL**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 1005 Edwardsville Road, Wood River, Illinois 62095, USA.

STORERIA DEKAYI WRIGHTORUM (Midland Brown Snake). USA: MISSOURI: St. Charles Co: NE 1/4 Sec. 26, T48N, R7E, Ellis Island, Riverlands Road. 26 May 1993. J. Tucker. Verified by L. Page. Illinois Natural History Survey (INHS 10990). Adult taken DOR; new county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **JOHN K. TUCKER** and **CHARLES H. THEILING**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 1005 Edwardsville Road, Wood River, Illinois 62095, USA.

STORERIA OCCIPITOMACULATA OCCIPITOMACULATA (Northern Redbelly Snake). USA: ILLINOIS: Jersey Co: SE 1/4 Sec. 9, T6N, R13W, Pere Marquette State Park. 14 July 1993. R. Maher. Verified by L. Page. Illinois Natural History Survey (INHS 10989). Adult taken DOR. County record; extends documented range 103.2 km WNW from closest Illinois record (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298) in Bond County (INHS 8655-8658).

Submitted by **JOHN K. TUCKER, ROBERT J. MAHER**, and **JAMES B. HATCHER**, Illinois Natural History Survey, Long Term Resource Monitoring Program, 1005 Edwardsville Road, Wood River, Illinois 62095, USA.

STORERIA OCCIPITOMACULATA OCCIPITOMACULATA (Northern Redbelly Snake). USA: ILLINOIS: Kane Co: Max McGraw Wildlife Foundation, 1.02 km W Rt. 25 and 1.6 km S Rt. 72 (42°5'34"N, 88°16'1"W). 3 October 1993. F. T. Burbrink and A. K. Wilson. Verified by Lawrence M. Page. Illinois Natural History Survey (INHS 10974). New county record (Smith 1961, The Amphibians and Reptiles of Illinois, Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **FRANK T. BURBRINK** and **ALLAN K. WILSON**, Max McGraw Wildlife Foundation, P. O. Box 9, East Dundee, Illinois 60118, USA.

THAMNOPHIS PROXIMUS (Western Ribbon Snake). USA: NEBRASKA: Richardson Co: NE corner of Sec. 31, T2N, R18E in abandoned quarry on E side of road. 29 May 1993. C. Bridgewater, T. Leonard, J. Lokke, and J. Young. University of Nebraska at Omaha (UNO 350). Verified by James D. Fawcett. New county record; southernmost occurrence of the species in Nebraska and helps fill in a large gap between populations occurring around the mouth of the Platte River in Nebraska and those to the south in Doniphan County, Kansas (Collins 1993, Amphibians and Reptiles in Kansas. Third ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 13:1–397; Lynch 1985, Trans. Nebraska Acad. Sci. 13:33-57.).

Submitted by **T. LEONARD**, 5006 South 36th Avenue, Omaha, Nebraska 68107, USA.

TROPIDOCLONION LINEATUM (Lined Snake). USA: COLORADO: Elbert Co: 100 m S County Road 194, 1 km W jct County Road 29. 19 September 1993. Hobart M. Smith, David Chiszar and Adam Chiszar. Verified by Richard L. Holland. UCM 56849. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver. 131 pp.).

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA, and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 90309-0345, USA.

New County Records Of Amphibians And Reptiles From Northeastern Texas

Dixon (1987 Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station, Texas. 434 pp.) updated the distribution maps for all Texas amphibians and reptiles. However, documentation for many species common to northeastern Texas is still lacking from various counties within the region.

From 30 April to 2 May 1993, the Texas Herpetological Society held its annual Spring Field Meet on the Caddo National Grasslands north of Bonham, Fannin County, Texas. The purpose of this gathering was to provide the U.S. Forest Service with a list of species occurring on the grasslands. During this meet, ten new county records were documented. In addition, seven records for northeastern Texas were also collected incidentally from 1987 until 1993. Voucher specimens for all species were deposited in the University of Texas at Arlington Collection of Vertebrates (UTACV), and are reported herein.

We herein document seventeen new county records for northeastern Texas and fill distributional gaps for sixteen species of reptiles and amphibians. Specimens from Fannin County were collected by us and other members of the Texas Herpetological Society during the course of the field meet. Records from other counties were collected by or donated to us. Verification of specimen identification was by Jonathan A. Campbell.

ANURA

Gastrophryne carolinensis (Eastern Narrowmouth Toad). Fannin Co: Coffeemill Lake, Caddo National Grasslands. 30 April 1993. UTA-A 40288–40291.

Rana areolata (Crawfish Frog). Hunt Co: 1.3 km SW jct FM 1565 on Grande Verde Road. 13 June 1987. UTA-A 32847.

Rana palustris (Pickerel Frog). Fannin Co: Coffeemill Lake, Caddo National Grasslands. 1 May 1993. UTA-A 40293.

Scaphiopus holbrookii (Eastern Spadefoot). Fannin Co: Coffeemill Lake, Caddo National Grasslands. 1 May 1993. UTA-A 40292.

TESTUDINES

Pseudemys concinna (River Cooter). Fannin Co: Lake Fannin, Caddo National Grasslands. 1 May 1993. UTA-R 34942.

Terrapene carolina (Eastern Box Turtle). Franklin Co: 13.2 km N of Mt. Vernon on SH 37. 9 May 1993. UTA-R 34939.

LACERTILIA

Anolis carolinensis (Green Anole). Fannin Co: Coffeemill Lake, Caddo National Grasslands. 30 April 1993. UTA-R 34932.

Eumeces laticeps (Broadhead Skink). Fannin Co: Lake Fannin, Caddo National Grasslands. 1 May 1993. UTA-R 34933.

Ophisaurus attenuatus (Slender Glass Lizard). Fannin Co: 2.6 km E jct FM 100 on FM 409, Caddo National Grasslands. 30 April 1993. UTA-R 34931.

SERPENTES

Diadophis punctatus (Ringneck Snake). Collin Co: Brockdale Park, Lake Lavon. 25 April 1987. UTA-R 28890; Fannin Co: Lake Fannin, Caddo National Grasslands. 1 May 1993. UTA-R 34795.

Heterodon platirhinos (Eastern Hognose Snake). Red River Co: 1.5 km E jct SH 37 on FM 1159. 18 April 1993. UTA-R 34930.

Nerodia fasciata (Southern Water Snake). Fannin Co: Coffeemill Lake, Caddo National Grasslands. 1 May 1993. UTA-R 34936, 34937.

Regina grahamii (Graham's Crayfish Snake). Delta Co: jct FM 1531 on SH 24. 8 May 1993. UTA-R 34938.

Storeria dekayi (Brown Snake). Collin Co: 4.8 km E of Wylie on Stone Rd., Beaver Creek Estates. 5 August 1992. UTA-R 33784.

Tantilla gracilis (Flathead Snake). Fannin Co: Lake Fannin, Caddo National Grasslands. 1 May 1993. UTA-R 34934, 34935.

Thamnophis sirtalis (Common Garter Snake). Lamar Co: Patonville. 1 September 1991. UTA-R 34929.

Acknowledgments.—We thank Texas Herpetological Society members Terry Hibbitts, Robert Hibbitts, Robert Lang, Charles Swift, Gary Ferguson, and Lynzie Herman for specimens donated. We also thank Jerry Shaffer and Jason Francis for the donation of the specimens of *Storeria* and *Thamnophis*, respectively. Travel expenses were, in part, paid from a grant from the University of Texas at Arlington chapter of Phi Sigma. Collections made on the Caddo National Grasslands were under the authority of a Temporary Special Use Permit granted by the U.S. Forest Service and authorized by District Ranger Ben T. Harbour.

Thirty-Five New Herpetological County Records For Texas

A review of some of the herpetological material in the West Texas A & M University Museum (WTAMU) has revealed several new county records supplementary to those in Dixon (1987, Amphibians and Reptiles of Texas. Texas A & M Univ. Press, College Station, Texas. 434 pp.) and in more recent entries in *Herpetological Review*. We here report new records for one species of anuran, three of lizards, and ten species and subspecies of snakes. All identifications were verified by Flavius C. Killebrew.

ANURA

Gastrophryne olivacea (Great Plains Narrowmouth Toad). Lamar Co: Blackwater River Park. 9 June 1983. T. James. WTAMU 8994; Randall Co: 19.2 km E Canyon, Rt. 217. 1 July 1987. John Sellers. WTAMU 12494 and southern Amarillo. 23 April 1981. Stacey Foster. WTAMU 14527; Stephens Co: Rt. 717, 11.3 km NNW Rt. 180. 3 May 1969. R. McKown. WTAMU 2374-6. The Randall County records extend the known range of the species about 55 km northwest of the nearest previous records in Briscoe (Dixon 1987) and Donley [Schafer and Kasper 1989, Texas J. Sci. 41(3):337–338] counties.

LACERTILIA

Crotaphytus c. collaris (Eastern Collared Lizard). Deaf Smith Co: 3.2 km E Hereford, Rt. 60. 22 April 1979. S. Grimsley. WTAMU 5006; Gray Co: Pampa city dump. 5 July 1970. A. Clark. WTAMU 1066; Sun Oil Camp, 11.3 km W Lefors. 17 June 1987. Jason Whatley. WTAMU 12358; Grayson Co: Lake Texoma. 25 September 1986. J. Vines. WTAMU 9958; Walker Co: Sam Houston National Forest. 18 March 1972. B. Benson. WTAMU 2516. The Gray and Walker county records extend the known range of the species eastward, the former ca. 40 km, the latter ca. 100 km (Dixon 1987).

Eumeces obsoletus (Great Plains Skink). Carson Co: Skellytown, Skelly golf course. 6 June 1966. Mary Burcham. WTAMU 46; Rt. 60, 8 km E Panhandle. 27 April 1987. Mark and Renae Haiduk, Don Roark. WTAMU 10570-3.

Scincella lateralis (Ground Skink). Karnes Co: Rt. 239, Choate. 16 May 1982. Jay Long. WTAMU 8731; Mills Co: P. K. Caraway Ranch, 6 km E jct Rts. 16 and 3023. 21-23 April 1977. Jeff Bertl, R. Brantley, P. Chance, Janice Geffhen T. Morris, Becky Norton, R. Richardson. WTAMU 2999, 3066, 3196, 3341-2, 3416-7, 3464, 3530; Pecos Co: Rt. 349 near Pecos River. 24 April 1977. T. Ellerbrook. WTAMU 3285. The latter record extends the range of the species in Texas westward from the adjacent county (Crockett) on the east (Dixon 1987).

SERPENTES

Diadophis punctatus arnyi (Prairie Ringneck Snake). Armstrong Co: Methodist Church Camp, Ceta Canyon. 10 October 1978. Burgi Lehmann. WTAMU 5317; Carson Co: Groom, McCoy Farm. 4 May 1985. Jay Vines. WTAMU 13983; Dallam Co: Seagraves ranch, 32 km S Texline. 1 June 1985. M. and J. Smith. WTAMU 13984, 14246; Hansford Co: Gibner ranch, 16.3 km N Spearman, Palo Duro Creek. 21 August 1976, 12 August 1978. Flavius C. Killebrew. WTAMU 5512, 5684; Mills Co: J. M. Wrinkle, Jr. ranch, Rt. 84, 14 km E jct Rts. 16 and 3023. 22 April 1977. M. Tucker. WTAMU 3120; Potter Co: Bishop Hills, off Rt. 1061. 28 September 1973. M. Meriage. WTAMU 2450; Canadian River, 24.1 km N Amarillo. 3 October 1985. B. Loving, G. McDonald. WTAMU 13767; Rt. 1061, 8.7 km W Rt. 66, then 1.25 km N. 15 April 1979. Ken Brewer. WTAMU 5879; Lake Meredith Plum Creek Recreation Area. 21 May 1983. Jim and Jay Vines. WTAMU 14293-4 and Lake Meredith, McBride Canyon, Rt. 136. 28 April

1987. M. Willis. WTAMU 10654; Wheeler Co: Camp M. K. Brown, Rt. 3182, 8.5 km N Rt. 152. 3 and 10 October 1981. T. Green, T Quezada. WTAMU 6823-4.

Diadophis punctatus stictogenys (Mississippi Ringneck Snake). Gonzales Co: Ottine. 10 August 1987. John Ingle. WTAMU 12589. Extends known range of the subspecies southwest ca. 80 km from the nearest previous record in Colorado County (Dixon 1987: 240) and about an equal distance from the nearest records for *D. p. arnyi* in Bexar and Hays counties. (Dixon, *loc. cit.*). The specimen clearly represents *D. p. stictogenys*, having 15 anterior dorsal scale rows and most ventral spots paired. It does not appear to be an intergrade.

Heterodon n. nasicus (Plains Hognose Snake). Foard Co: 3.2 km W Crowell, Rt. 70. 23 October 1983. Tom Adams. WTAMU 9427; Hemphill Co: 16.3 km E Canadian, Forgey ranch. 11 June 1973. Miles Rhea. WTAMU 5272; 6.5 km N Glazier, Rt. 305. 28 October 1981. Jeff Bertl. WTAMU 7954; Lipscomb Co: 8 km E and 1.6 km N Follett. 14 July 1986. Joel Babitzke. WTAMU 10536; Moore Co: Albates Park, 8 km S Fritch. 2 September 1981. T. D. Giovanni. WTAMU 7195; Ochitree Co: 8 km E Perryton. 1 October 1979. William May. WTAMU 6018.

Heterodon platirhinos (Eastern Hognose Snake). Childress Co: 26 km E Memphis, Rt. 256. 19 September 1981. Jay Long. WTAMU 6956; Floyd Co: 16.2 km SW Quitaque, Rt. 1065. 22 October 1985. Clinton Pigg. WTAMU 11595; Karnes Co: 9.4 km W Choate, Rt. 239. 9 October 1982. Jay Long. WTAMU 8780; Moore Co: Lake Meredith, Plum Creek. 8 November 1986. Rod Goodwin. WTAMU 10669.

Lampropeltis getula holbrooki (Speckled Kingsnake). Lee Co: Rt. 21, 6.5 km S Old Dime Box. 6 June 1982. Jay Long. WTAMU 8777. Although the locality lies within the intergrade area (as depicted by Dixon 1987:253) between *L. g. holbrooki* and *L. g. splendida*, this particular specimen agrees fully with the former subspecies.

Lampropeltis getula splendida (Desert Kingsnake). Briscoe Co: Quitaque. 1 November 1981. D. Brooks. WTAMU 7428.

Rhinocheilus lecontei tessellatus (Texas Longnose Snake). Reagan Co: jct and Rt. 137. 20 June 1970. B. Cox. WTAMU 742.

Sonora semiannulata (Ground Snake). Collin Co: western Plano. 5 June 1988. D. Porter. WTAMU 13717. The locality lies on the eastern edge of the range of the species (Dixon 1987:269).

Storeria dekayi texana (Texas Brown Snake). Oldham Co: Boys Ranch, at Elementary School and Junior High Gym. 27-29 July 1991. Eddie Taylor. WTAMU 14417-8; Randall Co: Cleta, Palo Duro Canyon. 24 August 1979. Jeff Bertl. WTAMU 6478. These specimens extend the known range of the species westward in northwestern Texas ca. 150 km, and indicate that the records for Lubbock and Crosby counties, questioned by Dixon (1987:270), may well be valid. We suggest that the range of the species in the area indicated follows major river valleys and does not include much if any of the intervening territory.

Tantilla nigriceps (Plains Blackhead Snake). Carson Co: Brooks ranch, 8 km S Skellytown. 5 April 1985. M. Smith and J. Smith. WTAMU 14267.

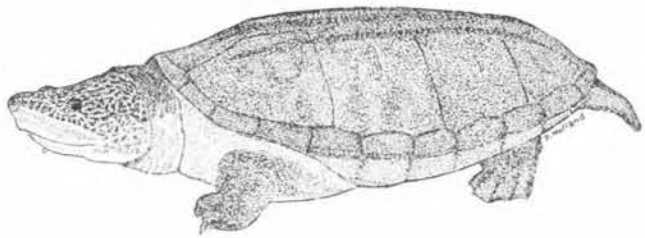
BOOK REVIEWS

Synopsis of the Herpetofauna of Mexico, Volume VII, by Hobart M. Smith and Rozella B. Smith. University Press of Colorado (P.O. Box 849, Niwot, Colorado 80544, USA), 1993, 1089 pp, cloth bound. US $50. ISBN 0-87081-284-x.

The taxonomic and ecological diversity of amphibians and reptiles in the Republic of México is perhaps unequaled in the world, and those herpetofaunal riches have been a major preoccupation of North American, and lately Mexican biologists. In the scant 60+ years since Edward H. Taylor and Hobart M. Smith began to reveal the wonders of Mexican amphibians and reptiles to the herpetological community, there has been continuous and ever increasing study of that marvelous fauna. One result of this massive application of attention from herpetologists, both native and foreign, is a massive literature. The literature on amphibians and reptiles of México is so vast that it seems beyond belief that it could be compiled, much less organized and indexed. But Hobart and Rozella Smith accepted the challenge, and Volume VII of the *Synopsis of the Herpetofauna of Mexico* concludes the most ambitious herpetological bibliography project ever undertaken.

This terminal volume consists of two parts: the fourth addendum to the base bibliography, and taxonomic indices to bibliographic addenda II through IV. The bibliographic addendum lists an additional 6606 titles pertinent to Mexican herpetology, bringing the total of titles compiled to 17,771. The coverage is exhaustive. Many titles are from the "gray literature," works not published in the technical sense of the word. In this category are abstracts of papers presented at meetings, internal research reports of government agencies, and theses and dissertations. It can be argued that these usually inaccessible "publications" should not be listed. However, they can provide clues to the existence of research in progress or completed but not published. The extensive listings of theses from Mexican institutions and titles from relatively obscure Mexican journals is a potentially valuable resource. The bibliography includes literature from 1979 (some 1979 references were included in addendum III) through May, 1991.

Each of the eight order-group taxa of amphibians and reptiles that occurs in México has a separate index chapter. Each of these chapters consists of an introduction, a taxonomic index, and a synonym list. The introduction to each chapter reviews taxonomic innovations in the group since the appearance of the last index in the series (Volume IV, 1976), and states the author's position on them. These positions are varied—from rigid conservatism to ready acceptance of controversial proposals. For example, on the conservative side Smith prefers to retain the genera *Tomodactylus* and *Syrrhophus*; however, he embraces the concept of removing *Pseudacris cadaverina*, *P. crucifer*, and *P. regilla* from *Hyla*. Nevertheless, the introductions are interesting reading. They reveal the thought processes of the author as he views modern taxonomic work on Mexican amphibians and reptiles from the perspective of a long-time major practitioner of the art. But most of the decisions are logically defended, and unreasoned support of the status quo is minimal.



The species indices include some welcome changes. The name of the first author is cited for each entry, along with the identification number of the reference and the page number. Each index entry is identified as being from Bibliographic Addendum II, III, or IV. Each index includes generic names and their synonyms, species, subspecies, and names spelled incorrectly. The synonyms and invalid names are followed in parentheses by the combination accepted in this work. The indices are alphabetical. Cross indices to species combinations, subspecies combinations, and state occurrences, and the valid name list have been omitted. In place of a valid name list the final section of each chapter is a

list of names generated from the index. Surely, as the author notes, each includes all or nearly all the valid names available.

The author states that with this volume their "attempt to summarize in detail knowledge of the herpetofauna of Mexico ends, with the task scarcely started." So ends an era, an era marked by the effort of Hobart and Rozella Smith to provide a solid foundation for further study of the Mexican herpetofauna. The *Synopsis of the Herpetofauna of Mexico* is a fitting memorial to their dedication.

Herpetofauna Mexicana. Annotated List of the Species of Amphibians and Reptiles of Mexico, Recent Taxonomic Changes, and New Species. By Oscar Flores-Villela, edited by C. J. McCoy. 1993. ISBN 0-91-239-42-1. Carnegie Museum of Natural History, Special Publication No. 17, iv+73 pp. US $15 (softcover).

The core of this work is a 23-page list of names of Mexican amphibian and reptile species in a two-column format. The first column lists the scientific names, alphabetized by families, and includes their authors and publication dates. Some of the names are followed by superscript numerals keyed to the section on "Notes to the species list" which follows the checklist. The second column contains a wealth of information about each taxon, including whether it is endemic to México, parthenogenetic or monotypic, plus its general distribution in México, all this condensed in a conveniently-coded system. For example, the entry for the indigo snake (*Drymarchon corais*), reads: "+ N; 1, 2, 3, 4, 5, 6, 7, 9, 10." The "+" means monotypic, the "N" means non-endemic, and the numbers are keyed to the general biogeographic areas discussed in the extensive Introduction and depicted in Fig. 2, a map of México.

This section is followed by a list of species that may (or may not) occur in México but for which there are no actual specimens or reliable published records. A five-page section on notes on the species list follows, which itself is followed by a 25-page list of "Recent taxonomic changes and new species," which includes an 11-page list of species described or first recorded from México since 1966, and a list of taxonomic changes at the species level which occurred since 1976. The last two sections deal with changes above the species level and changes in type-localities; both occupy less than six pages. The Acknowledgments and Literature Cited sections conclude the work.

This is the first attempt to summarize México's herpetofauna in almost 30 years, following the works of Smith and Taylor (1966) and Smith and Smith (1976a, 1976b). The author is to be commended for his courage in undertaking the summary of what amounts to almost 1,000 species, whose literature is scattered in all sorts of little-known journals. The herpetofauna is an extremely interesting one, with over 55% of the species endemic to México, a number that is likely to increase with the exploration of little-known or inaccessible areas. Some of the species, such as the Mexican axolotl, have been extremely well studied, while others are known only from the holotype. Here is a place where much work remains to be done, especially field studies by local or resident naturalists. It is extremely encouraging to see that this trend has been increasing rapidly in the past few years. The bilingual format of Oscar's work certainly makes it easier for exclusively Spanish-speaking Mexicans.

I cannot comment on the accuracy or completeness of the species list since México is not my geographic area of expertise. A sizable number of people reviewed it, however (I saw the first draft in the early 80's), so I assume it is as correct and complete as any checklist can be. The alphabetical (as opposed to phylogenetic) placement of genera under families makes the work easy to use, especially with large families. The author was selective in updating taxonomic changes although one may disagree with his selections. For example, he left all the anoles in one genus, but accepted the splintering of *Bothrops* and the Iguanidae, both of which have generated much controversy, while explicitly not accepting the rearrangement of the Centrolenidae (Ruiz-Carranza and Lynch 1991), which has not been controversial and has even been incorporated in the current herpetology textbook (Zug 1993).

I have two major, and a few lesser, criticisms of this work, and I write this with great hesitation since I respect Oscar's work and dedication, and he is my *compadre*. I do so only in a constructive way, hoping that a second edition can improve upon the first.

My main gripe pertains to the citation of the literature; it looks like the work of a committee rather than an individual. There are actually *three* major forms of literature citation! One is the "formal" Literature Cited, in which references are listed in the standard way. One would expect this to be a rather large section, but it is actually barely over a page long. The second is an in-text citation, which lists the author[s], date, title (in some cases), and journal or book reference. Some of the titles are quite long and pertain to unpublished theses done in México; these citations are duplicated due to the bilingual text, thus a lot of space is wasted. The third type of citation is the *Op. Cit.* type, which I find most problematic. For example, on page 44 I found a reference to "Villa et al. (1988, *op. cit.*: 63)." Because I didn't remember making the statement attributed to me, I had to work backwards through a number of similar "opcits" all the way back to page 39, where my memory was refreshed. My suggestion: make citations uniform to save time and space.

A second gripe is the exclusion of subspecific names. Granted, the list is clearly a *species* list, and including subspecies would have probably tripled the number of taxa listed. I could be accused of criticizing the same decision I myself made (to include or exclude subspecies) when compiling *Middle American Herpetology* (Villa et al. 1986). However, that was before Frost and Hillis' 1990 paper, and before Collins' (1991) proposal to elevate a number of allopatric North American subspecies to specific status. Although this proposal has generated considerable controversy, it may be accepted eventually, and a Mexican equivalent of J. T. Collins, if one can exist, may make a similar proposal for comparable Mexican subspecies. Thus, having the subspecific names available in an updated list becomes important.

One minor complaint pertains to the supposed bilingualism of the *Herpetofauna*. The text is bilingual throughout, except for the three sections on recent taxonomic changes. The introduction and the subtitles to these sections are bilingual, but the text itself is in English only. Some entries can easily be figured out, and

involve only a few lines, but many take up 10 lines or more. What went wrong here? If anything, the *opposite* should have occurred. This section involves some 25 pages, over 30% of the entire work. How will this be received in México?

The work's subtitle is a bit misleading, as it states it contains "Recent taxonomic changes, and *new species*" (my italics). I expected to find a number of new species described from México, but there are none. Either the new species were deleted from the work at the last minute and the subtitle not changed, or the "new species" refers to the listing of "Species described or first recorded from Mexico since 1966." The advertisement mailed by the Carnegie Museum lacks the subtitle, and makes no claims about any new species.

Herpetofauna Mexicana is a work large enough to merit a dedication, but it has none. This would have been an excellent opportunity to honor the two major Mexican herpetologists who recently passed away, Miguel Alvarez del Toro and Rafael Martín del Campo.

My last gripe is the price. Fifteen dollars is a lot of money to pay for an 80-page booklet, even for one as nice as this one, with glossy paper and octavo format. I hope that the Carnegie made some arrangements for a lower price in México, otherwise many local herpetologists will not be able to buy a copy.

Criticisms aside, *Herpetofauna Mexicana* is a major contribution to the knowledge of the herpetology of our neighbor to the south, and should facilitate—if not encourage—the work of others, both local and foreign. Anyone who has put together a checklist of similar magnitude knows how much devotion and work goes into it, how tedious and interminable the work can be, and how thankless the task is. Thank you, Oscar, for undertaking it; I hope your skin is of the squamate sort, rendering you impermeable to criticism.

The Amphibians and Reptiles of Maine, by Malcolm L. Hunter, Jr., John Albright, and Jane Arbuckle (editors). 1992. Maine Agricultural Experiment Station Bulletin 838. 188 pp. US $9.95. (Paperback).

The editors claim two motives for producing this book. First, the passage of Maine's Endangered Species Act in 1984, in part, prompted them to determine the status of Maine's amphibians and reptiles. Second, was their hope to increase the appreciation of amphibians and reptiles by the people of Maine.

As you can well imagine, it is no small task to determine the status of all the amphibian and reptile species of any state. The Maine Amphibian and Reptile Atlas Project (MARAP) was, evidently, the first such attempt by biologists in the state. A network of some 250 volunteers was established and enlisted to search for the presence of amphibians and reptiles. After about four years, the editors felt they had sufficient data to begin writing. They recruited volunteers to write individual species descriptions. Range maps were prepared based on the submittal of MARAP forms with three decreasing levels of confidence: a specimen was collected and preserved or photographed, a specimen was handled then released, or a specimen was seen or heard but not captured.

The book opens with two brief introductory chapters on the biology of amphibians and of reptiles. These are followed by a description of Maine's environment as habitat for herps and a summary of how the range maps were prepared. The main body of the text is descriptions of Maine's 18 species of amphibians, 19 species of extant reptiles, and the extirpated timber rattlesnake. The book closes with sections on finding and enjoying amphibians and reptiles; hypotheticals, accidentals, and other oddities; methods used in the MARAP; the distribution and abundance of herps in Maine; and conservation concerns.

There is very little new information about the amphibians and reptiles of Maine in this book. Most of the information comes from previously published sources, and because many different authors provided species accounts, the writing is uneven in content and in the use of citations. There is very little useable information on the density of any species in any one place.

The range maps offer information on the presence or absence of a species in the townships of Maine, but the operating premise (although unstated) is that at least one volunteer would examine suitable amphibian habitats in every township. This was not the case. I noticed that range maps for many of the abundant species were almost identical. The range maps for abundant species appear to this reviewer to be range maps of the locations of volunteers. With few exceptions, we learn from this type of survey that a species either occurs widely in the state or does not. Only the range maps for rare species may contain some kind of useful information for future comparisons, although I am not certain what that information is.

The illustrations are all black and white line ink drawings of generally poor quality and could not be used for identification purposes.

I know that other states in the northeast are using similar procedures to document the status of their herpetofauna. It seems to me for the information to be of use, much greater effort needs to be expended to determine not only whether a species occurs in the state, but we must systematically determine where the various species do and *do not* occur. The problem with MARAP-type surveys is that a species can only be found in an area if a volunteer happens to look there. In addition, as mentioned by the editors, rare species received more attention from volunteers than did common species, thus the data in some unknown way overestimate the abundance of rare species and underestimate the abundance of common species. A useful addition to the range maps would have been the collection location of

previously deposited museum specimens. Perhaps volunteer survey data taken together with more traditional surveys by working herpetologists would have provided more useful range maps.

A very important task for biologists today is to document systematically what are the densities of the region's fauna, because these will be the data needed in 10 or 20 years to determine whether or not a species has declined. It is unlikely that networks of volunteers can accomplish this task working alone. Even systematic surveys that result in unbiased measures of relative abundance provide data that can be used for comparative purposes over time.

The second objective of the book was to increase the appreciation of the state's herps by its citizenry. Because the book does summarize information on the species and is relatively inexpensive it may fulfill that objective.

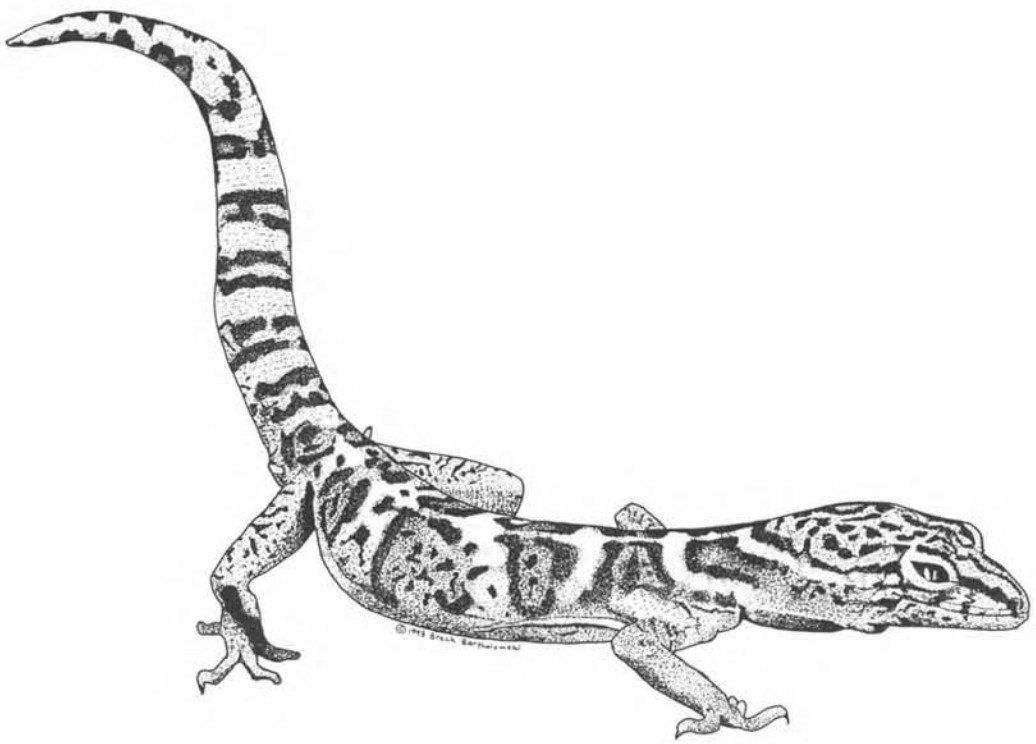
PUBLICATIONS RECEIVED

World Checklist of Threatened Amphibians and Reptiles, 5th edition, compiled by the World Conservation Monitoring Centre. 1993. Joint Nature Conservation Committee, Peterborough, U.K. vi + 99 pp. Softcover. £11.00 (approx. US $17). ISBN 1-873701-46-2.

A listing of those species of amphibians and reptiles listed in appendices I, II and III of CITES, and those included in the latest *IUCN Red List of Threatened Animals*. Included are 135 amphibian taxa in 19 families and 570 reptiles in 36 families. Each listing also provides commonly used synonyms (normally alternative generic assignments) and English language common names, when these exist. Countries, and sometimes less inclusive areas such as states, provinces, or mountain ranges where each species occurs are given. Each entry indicates the CITES appendix and/or Red List status of the taxon and references to general and regional literature on distribution, conservation status, and/or nomenclature are listed by number. A total of 738 references are included in the bibliography and the text is indexed by both common and Latin names. This edition includes many additional references and status updates with respect to the 4th edition (1988), but contrary to the previous version, does not provide information on the type of exploitation experienced by the species.



Amphibian Zooculture [in Russian] (many authors). 1990. USSR Academy of Sciences, Moscow. 120 pp. $8.00 + postage.

A collection of 13 papers dealing with a variety of topics associated with the captive breeding and maintenance of frogs and salamanders. Among the contributions included are papers on endocrine control of reproduction, growth in captivity, hybridization, conservation, reintroductions from captive stock, and human utilization of amphibians.

Trophology of Tailed Amphibians: Ecological and Evolutionary Aspects [in Russian] by S. L. Kuzmin. 1992. "Nauka" (Russian Academy of Sciences), Moscow. 168 pp. Softcover. $10.00 + postage. ISBN 5-02-005489-5.

A treatise on salamander feeding and trophic relations. Topics covered include methods of dietary analysis, niche dynamics and niche overlap, prey selection and optimal foraging, ontogenetic and evolutionary changes in diet, food as a limiting resource, and cannibalism. Examples are drawn from a wide variety of (chiefly temperate) salamander species and more than 750 references are cited. Illustrated by 23 figures, graphs, and charts.

Both publications are available from *Dr. Sergius L. Kuzmin, Institute of Evolutionary Morphology and Ecology of Animals, Russian Academy of Sciences, Leninsky Prospect, 33, Moscow 117071, Russia.*

Coleonyx variegatus variegatus. USA: Nevada: Clark Co., ca. 16 km S of Las Vegas. Illustration by Breck Bartholomew.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). ***HR*** especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints.

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes, and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of external reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

RWH

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc. RFD 6 Box 1, Lawrence, Kansas 66046. *Herpetological Review* is composed using Microsoft Word and Aldus PageMaker on Apple Macintosh computers. SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

Catalogue Of American Amphibians And Reptiles

The Catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 555	$270.00
INDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages	$5.00
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$6.00
IMPRINTED POST BINDER: (*Note:* one binder holds about 200 accounts)	$35.00
INCOMPLETE SET: NUMBERS 1 - 190	$75.00
191 - 410	$85.00
411 - 555	$110.00

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology***. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1993

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*
Institutional subscription	$60.00		

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired.). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

1994 Annual Meeting
Society for the Study of Amphibians and Reptiles
37th Annual Meeting
being held jointly with
The Herpetologists' League

28 July–1 August 1994

The University of Georgia, Athens, Georgia

Hosted by the University of Georgia Museum of Natural History and The Savannah River Ecology Laboratory

Meeting Announcement: All interested persons (members of SSAR or HL or non-members) are welcome to attend the 1994 meeting. All attendees must pay the registration fee. The full meeting announcement, description of activities, call for papers, pre-registration form, and full information on accommodations will be mailed to SSAR and HL membership no later than March 1994. For information in the interim, write the local committee Project Coordinator, Amy Edwards, Museum of Natural History, University of Georgia, Athens, Georgia 30602-1882, USA (706-542-4137; during weekday business hours (Eastern); FAX: 706-542-3920). Overseas members will not automatically receive the meeting announcement, but may request a mailing by writing or calling Amy Edwards.

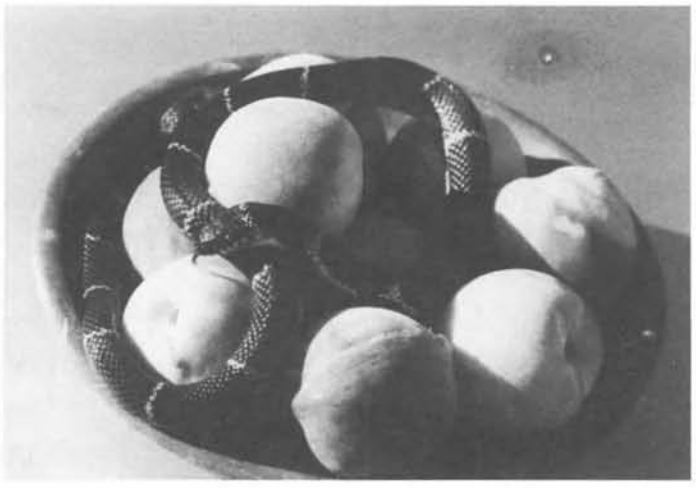
Plenary Session: The meeting will begin with a Plenary Session at 9 AM on Thursday, 28 July. The Keynote address will be given by the 1994 Distinguished Herpetologist, Dr. Richard Shine ("The Evolution of Reptilian Viviparity Revisited").

Symposia: Three symposia, one colloquium, and one evening forum are planned. For further information on the forum, colloquium, or symposia, please contact the organizer directly.

Forum: "Issues in Conservation: Point-counterpoint" (Moderator: Robert Jaeger. Speakers: Henry Wilbur and Brad Shaffer. Sponsored by SSAR and HL).

Colloquium: "Turtle Phylogeography" (Organizer: Brian Bowen. Sponsored by the UGA Museum of Natural History).

Symposium: "Field and Behavioral Endocrinology" (Organizer: Diana Hews. Sponsored by SSAR and HL).



Symposium: "Interfaces Among Inter-individual Variation, Life Histories, and Population Dynamics of Reptiles and Amphibians" (Organizer: Art Dunham. Sponsored by HL).

Symposium: "West Indian Herpetology: A Symposium in Memory of Albert Schwartz" (Organizers: Robert Powell and Robert W. Henderson. Sponsored by SSAR).

Contributed Papers & Poster Sessions: There will be several concurrent sessions each day of the meeting. All sessions will be held in rooms at the Georgia Center. Contributed papers and Poster presentations require submission and acceptance of an abstract. US, Mexican, and Canadian members of SSAR and HL will receive the call for papers and abstract submission instructions by the end of March, 1994. Deadline for abstract submission is 15 May 1994. The space for oral presentations and posters will be allotted on a first come, first served basis. Authors will receive written confirmation of their presentations in late June. Questions concerning paper or poster sessions should be directed to Martina Conrad, Savannah River Ecology Laboratory, P.O. Drawer E,

Live Oak Forest, Sapelo Island, Georgia.

Georgia is known both for its peaches and its snakes!

Aiken, South Carolina 29802, USA (telephone 803-725-2472; FAX 803-725-3309; email CONRAD.SREL.EDU).

Student Paper Awards: There are two student paper competitions: SSAR's Seibert Awards for outstanding student presentations and the Herpetologists' League Award for Graduate Research. Winners of the Seibert Awards for the two best orally-presented student papers will receive $250 for first and $150 for second place. The winner of the Herpetologists' League Award for Graduate Research will be presented with $500 and ten years of back issues of *Herpetologica*, plus an invitation to submit an expanded, full-length manuscript to *Herpetologica* for publication. Details on how to compete for these two awards will be included in the meeting announcement.

Pre-registration: $115 for non-students and $80 for students registering before 20 June. Registration after that date will be $160 for everyone. Registration fees cover all administrative costs, printing of conference materials, refreshment breaks, evening socials, and miscellaneous expenses. All participants must register, including spouses and others that wish to attend meeting sessions, socials, or other programs.

Registration: On-site registration at the University of Georgia Center for Continuing Education will begin Wednesday, 27 July, from 4 PM to 7 PM. Registration will be open again on Thursday from 8 AM to 5 PM.

Social Programs:

Welcome social Thursday night, 28 July.
Graduate Students ONLY program and social Friday, 29 July.
Multimedia presentation Friday, 29 July.
Barbecue picnic at the State Botanical Gardens Saturday, 30 July, featuring one of Athens' favorite bands, *The Normaltown Flyers*.
Annual SSAR Auction Sunday, 31 July.
SSAR President's Travelogue (slide shows of exotic herps and habitats) Monday, 1 August.
Herptile art exhibit at the Institute of Ecology, Friday to Monday.
Live animal exhibit of southeastern reptiles and amphibians presented by SREL.

Field Trips: Arrangements are being made for five field trips, which will begin on Tuesday, 2 August. They include: Zoo Atlanta/Braves Baseball Game, Okefenokee Swamp, Savannah River Ecology Laboratory, Highlands Biological Station, and Sapelo Island. There are only a limited number of spaces for each trip, and participants must register ahead of time.

Family Programs: The University of Georgia recreational facilities at Lake Herrick may be used by participants of the meeting for a small fee. The facility includes a lake for swimming, short nature trails, and fields for playing sports. Children under 18 must be accompanied and supervised by adults. Other recreation facilities on campus include racquetball, squash, tennis and basketball courts, swimming pools and weight rooms. In addition there are several parks and recreational areas in Athens that have programs for children and parents. A variety of child care and children's programs will be available for nominal fees. A number of morning tours are being organized for spouses, including tours of the University Campus, historical sites in Athens, antebellum homes in Madison, and the State Botanical Gardens. More specific information on these programs will be included in the meeting announcement.

Climate: The summer months in Athens are usually filled with hot days and occasional afternoon thunder storms. Light summer clothing is appropriate in the day and evening.

"Gator Pond" on Sapelo Island, Georgia.

Collecting Permits: Collection of reptiles and amphibians for scientific or educational purposes in Georgia is regulated by the state's Department of Natural Resources. A permit for scientific collecting purposes, and a resident non-resident hunting/fishing license for recreational take are required. Direct inquiries for scientific permits to: Special Permit Unit, Georgia Department of Natural Resources, Game and Fish Division, 2070 U.S. Hwy 278 S.E., Social Circle, Georgia 30279, USA (permit information: 404-918-6404; other information: 404-918-6400).

Upper Three Runs Creek, Savannah River Site, South Carolina.

Accommodations: All housing reservations will be handled by the Georgia Center. There are rooms available at this facility and nearby hotels as well as in the University dormitory. UGA dormitory prices are: $25/night single and $30/night double occupancy. Current room charges for the Georgia Center range from $45/night for single occupancy in a room with two twin beds, to $55/night for double occupancy in a room with one queen-sized bed. Off campus hotels range in price from $42/night to $55/night. Space in these locations is available on a first come first served basis. Athens hosts a number of meetings during the summer, so making early reservations is strongly recommended. Questions concerning registration and accommodations should be directed to: Norma Reed, Conferences, Georgia Center for Continuing Education, University of Georgia, Athens, Georgia 30602-3603, USA (phone 706-542-6658).

Meals: Registrants may purchase University dining facilities meal tickets for breakfast, lunch, and dinner on Thursday through Monday. These may be purchased *in advance only* when pre-registering. In addition, there are a number of local restaurants in downtown Athens that are a short to moderate walk from the Georgia Center. Participants are encouraged to purchase meal tickets and use the conveniently located University facilities for breakfast and lunch.

Transportation and Parking: The University of Georgia is located on the edge of downtown Athens. Athens is just 66 miles east of Atlanta, Georgia. Athens is bisected by a number of state highways and US highway 78, and is just south of Interstate 85 and north of Interstate 20. Participants staying at the Georgia Center or the dormitory will be able to park at the Center's parking deck for a small fee.

Athens has a local airport just 15 minutes from campus. It is served by USAir from Charlotte, North Carolina ONLY. Shuttle transportation from the airport is provided by the local hotels or taxi. Participants may also fly into Atlanta International Airport. AAA, a privately owned and operated shuttle, carries passengers from Atlanta to Athens for approximately $45 round trip. Reservations must be made ahead to reserve a space on the shuttle; mention the SSAR/HL meeting for a 10% discount (phone: 800-354-7874 FAX: 404-767-9150).

Inhabitants of "Gator Pond."

Questions concerning registration and hotel reservations should be directed to Norma Reed, Conferences, Georgia Center for Continuing Education, University of Georgia, Athens, Georgia 30602-3603, USA (telephone 706-542-6658; FAX 706-542-5990; email REEDN@GACSRV.GACTR.UGA.EDU).

Questions concerning paper or poster sessions should be directed to Martina Conrad, Savannah River Ecology Laboratory, P.O. Drawer E, Aiken, South Carolina 29802, USA (telephone 803-725-2472; FAX 803-725-3309; email CONRAD.SREL.EDU).

Questions concerning general program arrangements should be addressed to Amy Edwards, Program Coordinator, Museum of Natural History, University of Georgia, Athens, Georgia 30602, USA (telephone 706-542-4137; FAX 706-542-3920; email AEDWARDS@ZOOKEEPER.ZOO.UGA.EDU).

SSAR BUSINESS

SSAR Annual Meeting: Bloomington 1993

Bloomington, Indiana was the site of a gathering of over 300 herpetologists between 7 and 12 August 1993, as Indiana University hosted SSAR for its 36th annual meeting. The meeting was co-chaired by Craig Nelson and Michael Ewert of the local committee.

The annual meeting of the SSAR Board of Directors got things under way on 7 August 1993, between 1010 and 1840 hours (EST), in the Distinguished Alumni Room of the Indiana Memorial Union. A wide range of those minding SSAR's business were present: nine officers and Board members were there, as were editors from all but one of the Society's publications, several coordinators, and chairs or representatives of virtually all committees; an additional 10-12 interested members rounded out the attendance. A summary of business conducted was later presented at the Business Meeting (see below).

Presentations

Local Co-chair Craig Nelson officially called the meeting to order at 1230 hours on Sunday, 8 August 1993, and welcomed us all to Bloomington and the University. The welcome was followed by a few brief announcements, and then we were off to see the lizards! President Fritts introduced our Keynote Speaker, Walter Auffenberg, of the Florida State Museum, who presented "Feeding Strategies of Monitor Lizards." Following the keynote address Amy Edwards made a brief presentation on next year's Annual Meeting, to be held 28 July to 1 August 1994 at the Georgia Conference Center, University of Georgia, Athens.

Dr. Auffenberg's exciting and informative discourse on monitor lizards was condensed from almost 25 years of study of the giant lizards. Walt noted that his real love was feeding ecology and the three species that were the subject of this address, the Komodo, Grey's, and Bengal monitors, all exhibited different feeding strategies. Although the juveniles are "almost boringly the same"—insectivores—the adults are all specialized to utilize different prey. With a mock sneer at those who study *Anolis* or *Sceloporus*, he noted the excitement of working with a 10 foot long, 140 pound dominant male Komodo monitor! Komodos are found mostly in lowland habitat, with a home range of up to 7 square miles. Adults are adapted for killing large prey, consume an average of 3 kg per minute, and can completely devour a water buffalo in three days, though deer are their preferred prey. Grey's monitor, ranging to 5.5 feet and 20 pounds, is found in mesic montane forest, and even climbs high into trees. Feeding on mollusks and the oily fruits of just over a dozen forest plants, their horizontal home range only averages 2 hectares, although there is a significant vertical component to their activities. The Bengal monitor is much more widespread than either of the others. Also unlike the other two species, the adults pretty much maintain juvenile feeding habits. They are insectivores, most of whose prey is 10-20 mm in length, and is obtained from bovine manure (where insect abundance peaks 3 to 4 days post-deposition).

Seventy papers were contributed by 100 authors in seven sessions between 1445 hours, 8 August 1993 and 1700 hours, 11 August 1993. In addition, 75 authors presented 37 posters during three sessions. Three symposia (Carpenter, Grants in Herpetology, and Vision), involving 46 authors and 35 papers completed the official scholarly presentations.

Sociality

A busy schedule of additional events attests to the Hoosier hospitality SSAR was shown in Bloomington. These efforts by the local committee, and especially Craig Nelson, were well appreciated.

Many of us arrived in Bloomington on Saturday, whether our presence was necessary at the Board meeting or not. So, after adjournment of the Board meeting, we checked out some of Bloomington's fine eating establishments, many within easy walking distance. The events of Sunday evening certainly kept us busy. The group photo was taken just prior to the barbecue, at which plenty of food and drink were had by all. Then followed the second edition of the newly revived "President's Herpetological Travelogue," where, again, those of us with the interest but no opportunity to visit exotic shores vicariously enjoyed their herpetofauna. Aaron Bauer entertained us with the herps of Australia, New Zealand and New Caledonia; Tom Fritts illustrated the habitats and herps of the Galapagos; Norm Scott presented the herps of Costa Rica; and Harold Voris described "Borneo: herpetological paradise." A thoroughly enjoyable evening all around!

The next evening, Monday, was covered by the annual SSAR Auction, with Joe Collins as auctioneer. It was yet another year of liquid refreshments and wild bidding, but for a good cause and was a successful and entertaining evening. A number of individuals assisted at the auction; in addition to Treasurer Doug Taylor, there were Jim Baron, Ellin Beltz, Suzanne Collins, Mark Deutchlander, Chris Grimes, Ian, Gene Kapler, Karen Toepfer, and Jeanne Young.

The annual multimedia event rounded out the week's evening events on Tuesday. "Amphibians of the Appalachians" and "Herpetology of the American West" by David Dennis and Eric Juterbock, and "Herpetologists Past and Present" by Kraig Adler and Dave Dennis, played to a large and enthusiastic audience in the Whittenberger Auditorium of the Indiana Memorial Union.

The live exhibit of local amphibians and reptiles, long an SSAR tradition, and awaited by many of the photographically inclined, was held in the Jordan Hall atrium. This locality made for a lot of traffic and many school children found their way there during the week; perhaps we sowed the seeds of herpetology in a few of them! The live exhibit was sponsored by the Hoosier Herpetological Society, and offered us looks at several dozen local species. Also available throughout the meeting were a show of herpetological art at the Campus-Community Art Center; a number of commercial exhibits, offering such items as books, arts and crafts, and research and care equipment, in the Union; tours of the Indiana University axolotl colony; and, another SSAR innovation, a students only reprint scavenge. For this latter event, a number of established herpetologists brought selections of their reprints which were then made available free of charge to any student willing to scavenge through the piles of reprints.

Business Meeting

The Annual Business Meeting was called to order at 1705 hours, Tuesday, 10 August 1993, in the Georgian Room of the Memorial Union, by President Tom Fritts. Tom welcomed everyone to the meeting and made a few opening remarks.

Secretary Juterbock presented a very brief summary of business conducted at the Board Meeting and not reported by anyone else. SSAR, through the efforts of Ed Moll, and along with ASIH and Herp League, received a grant from NSF to cover some graduate student travel to the Second World Congress of Herpetology in Australia this winter. Most of the publications damaged last year in the St. Louis flood were shipped to México and India to institutions that could not generally afford to purchase them. Treasurer Taylor and Publications Secretary Aldridge noted the very significant problems caused by late renewals. Treasurer Taylor announced that SSAR was in good financial shape, that membership appeared to be stable, and that the budget was balanced without having to raise dues.

A brief summary of editorial business indicates that all publications are on time and in good financial shape. *Journal of Herpetology* anticipates a new format for the Table of Contents. *Herpetological Review* introduced its new format last year. The *Catalogue of American Amphibians and Reptiles* still has a significant problem in soliciting accounts. *Facsimile Reprints in Herpetology* will issue Fauvel's "Alligators in China" (1879) in October 1993 and Fitzinger's "Neue Classification der Reptilien" (1826) in fall 1994; *Contributions to Herpetology* will issue Zhao and Adler's "Herpetology of China" in October 1993 and the Conant Symposium volume "Conservation and Captive Management of Amphibians and Reptiles" in spring 1994. *Herpetological Circulars* issued Brown's "Biology, Status and Management of the Timber Rattlesnake (*Crotalus horridus*): A Guide for Conservation" in February 1993. There was discussion about beginning a new series of works in herpetological conservation.

Committee work of note included the Grants in Herpetology Committee discussing new categories for submission: travel, conservation of amphibians and/or reptiles, field research, laboratory research, and education; these categories will be effective for the 1995 SSAR Grants in Herpetology program. The Annual Meetings Committee is pursuing meetings in 1996 in New Orleans and 1997 in Seattle; the Board accepted an invitation to meet in Boone, North Carolina in 1995.

Amy Edwards (1994 Local Committee Coordinator) was available to answer questions about the 28 July–1 August 1994 meeting in Athens, Georgia. SSAR will meet jointly with the Herpetologists' League; the University of Georgia Museum of Natural History and the Savannah River Ecology Laboratory will co-host the meeting. Be sure to follow *Herp. Review* for news of the plans and descriptions of the site.

Secretary Juterbock, reporting for the Nominating Committee, announced the candidates for terms of office beginning in 1994. President-elect: Victor H. Hutchison and Alan H. Savitzky; Secretary: J. Eric Juterbock; Treasurer: Karen L. Toepfer; Director: Janalee P. Caldwell and Ellen M. Dawley; Director (Regional Herp Society): Paul E. Moler and Martin J. Rosenberg. With no nominations from the floor, Don Forester moved (Bob Hansen seconded) to close the nominations; the motion carried without dissent.

The only item of old business discussed was the revision of the SSAR Bylaws. The Board had previously approved amending the Bylaws to clarify a couple of procedures. Copies of the proposed changes were distributed to attendees, who also approved the changes. The proposed amendments will be voted on by the membership in the 1993 election. As new business, a call was made for proposals for symposia for the 1995 meeting in Boone. George Pisani read the resolutions proposed for adoption by the membership (see below).

Finally, at about 1740 hours, President Fritts presented the official SSAR Presidential Gavel to President-elect Houck, who adjourned the meeting.

1993 SSAR Resolutions

Honoring Outgoing SSAR Officers and Editors

WHEREAS the following individuals have given freely of their time, skills, insight, and knowledge to the Society for the Study of Amphibians and Reptiles in this past year; and,

WHEREAS they have been therefore instrumental in advancing the Society's goals and furthering its growth as an international scientific society; and,

Amphibians and Reptiles in Kansas

Third Edition, Revised

Joseph T. Collins

Photographs by
Suzanne L. Collins

- Extensively revised
- 96 color and 103 black-and-white photos of salamanders, frogs and toads, turtles, lizards, and snakes
- Standardized common names and current scientific names
- 94 maps showing range of species in Kansas
- Information about identification, size, breeding, food, endangered or threatened status when relevant, habits, and habitats

420 pages. $29.95 cloth,
$19.95 paper

University Press of
Kansas

2501 West 15th Street
Lawrence KS 66049
(913) 864–4155

WHEREAS SSAR is dependent upon the generosity of these persons and those who have gone before them, and is greatly indebted to them all for their fine efforts in its behalf;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles urges these persons not to withdraw from service, but rather to continue to be available, with or without official titles, as resources to guide those who follow; and,

RESOLVED FURTHER that the Society offers its most sincere thanks to the following persons who have served in these capacities:

WILLIAM S. BROWN— Chair, Long-Range Planning Committee
GUSTAVO CASAS-ANDREU— Director
CHARLES COSTA— Elector
STEVE CORN— *Herp. Review* section editor
DARREL FROST— *Herp. Review* section editor
STEPHEN H. HAMMACK— Chair, Regional Societies Liaison Committee and *Herp. Review* section editor
LYNNE HOUCK— *J. Herp.* Editorial Board member
JERRY JOHNSON— Co-Chair, 1992 Local Committee
CARL LIEB— Co-Chair, 1992 Local Committee
LINDA R. MAXSON— Immediate Past-President and *J. Herp.* Editorial Board member
EDWARD O. MOLL— President
HENRY R. MUSHINSKY— Director
HOBART SMITH— *J. Herp.* Editorial Board member
MARGARET M. STEWART— Chair, 1992 Nominating Committee
SAMUEL S. SWEET— Editor, *Journal of Herpetology*

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 10 August 1993 at its Annual Business Meeting.

Thanking The Local Committee

WHEREAS Indiana University at Bloomington has a long tradition of research in natural history and herpetology; and,

WHEREAS Indiana University at Bloomington has hosted this diverse assemblage of over 300 herpetologists at the 36th annual meeting of the Society for the Study of Amphibians and Reptiles; and,

WHEREAS Co-Chairs Craig Nelson and Michael Ewert obviously have worked long and hard to assure the success of this gathering as an intellectual and social event; and,

WHEREAS they have been assisted capably in this effort by John Philips, Jim Barron, Jean Capler, Pat Clark, Mark Deutschlander, Chris Grimes, Matt Klulowski, Wende Wente, Jennifer Alexander, Jake Streepy, Susan Barnett, Greg Delisle, Susan Duhon, Robert Webb, Patty Hooten, the members of the Hoosier Herpetological Society, and last— but by no means least—the staff of the Indiana University Conference Bureau;

THEREFORE, be it

RESOLVED that the Society for the Study of Amphibians and Reptiles extends its most sincere thanks to these several persons whose effort and attention to detail has made this meeting a success.

Adopted unanimously by the Society for the Study of Amphibians and Reptiles, 10 August 1993 at its Annual Business Meeting.

Kennedy Award Winner

The 1993 Kennedy Student Award, for student-authored papers published in volume 26 of the *Journal of Herpetology* is "The trade-mediated introduction of *Eleutherodactylus martinicensis* (Anura: Leptodactylidae) on St. Barthélémy, French Antilles, and its implications of Lesser Antillean biogeography" by Hinrich Kaiser. His present address is Redpath Museum, McGill University, 859 Sherbrooke St. W., Montréal, Québec, Canada H3A 2K6, and Department of Biology, McGill University, 1205 Penfield Ave., Montréal, Québec, Canada H3A 1B1. Hinrich's major professor is Dr. David M. Green of McGill University.

Twelve manuscripts were in competition this year. The Award Committee noted the high quality of the submitted papers. SSAR congratulates Hinrich Kaiser for his fine paper.

Seibert Awards

The second annual Seibert Awards were presented at the 36th Annual Meeting of the SSAR in Bloomington, 7–12 August 1993. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). The awards recognize outstanding student presentations at the annual meeting.

The winners:

First Place: T.U. Grafe (Section of Neurobiology and Behavior, Cornell University), "Graded calls and the function of call alternation in the African reed frog *Hyperolius marmoratus*."

Second Place: David J. Able (Section of Neurobiology and Behavior, Cornell University), "Correlates to male mating success in the red spotted newt (*Notophthalmus v. viridescens*)."

SSAR congratulates these students for their fine presentations.

Joint SSAR–HL Directory of Herpetologists

The societies are in the process of compiling a new directory. In order to ensure accuracy, we ask that you review the address label used to mail this periodical to you. Please make any corrections (or, indicate OK), add your phone number, FAX number, and E-MAIL address to the sheet (or, if you are reading this in *Herpetological Review*, remove the label from the cover and tape to an index card or sheet of paper) and return this information to: *Karen L. Toepfer, SSAR Treasurer, 303 West 39th Street, Hays, Kansas 67601-1518, USA.*

NEWSNOTES

AAZK Grants Available

The American Association of Zoo Keepers announces the availability of two $750 research grants in the field of zoo biology. The deadline for submissions is 1 March 1994. Interested applicants should direct their inquiries to: *Sue Barnard, Chairperson, AAZK Research/Grants Committee, Zoo Atlanta, Department of Herpetology, 800 Cherokee Ave. SE, Atlanta, Georgia 30315, USA.*

Boa Survey

Persons with captive adult *Boa constrictor* are requested to write for a questionnaire concerning captive reproduction. The questionnaire is available in English, Spanish, French, German, and Dutch. Even if your animals have not reproduced, please respond if they are at least 4 years old and have had the opportunity to breed. Respondents' names and addresses will be kept confidential and will not be used for any purpose other than this survey. In return for a completed survey you will receive a chart showing subspecies, their scale counts, and ranges. *William D. Joy, P.O. Box 821433, Dallas, Texas 75382-1433, USA. INTERNET: 72223.220@COMPUSERVE.COM.*

Southwestern Research Station Volunteer Program

Approximately 20 volunteer positions are open in 1994 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for 24 hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between 15 March and 1 November. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by 15 February, summer volunteers (June–August) by 1 April, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA; Tel. (602) 558-2396.*

Call For Commercial Breeders Of Amphibians And Reptiles

Eco-Zoo is a private conservation group helping to foster a greater union and long-term cooperation between the scientific community and private enterprise. The Herpetology Section of Eco-Zoo plans to publish a World Directory of Amphibians and Reptiles being produced for commercial purposes or potentially as such, in government research programs, scientific projects, private captive breeders, etc. Anyone wishing to appear in the directory should contact Eco-Zoo in writing for more information. Persons interested in receiving publication data on the directory should send the name of a contact person, type of business or institution, address, and phone number to: *Eco-Zoo, Herpetology Section, 2255 North University Parkway, Suite 15, Provo, Utah 84604-7506, USA.*

Move Of Biological Survey Collection, Fort Collins

The National Ecology Research Center announces the move of the Biological Survey Collection, Fort Collins, Colorado (BS/FC) to Albuquerque, New Mexico effective January, 1994. The collection will be relocated in the Museum of Southwestern Biology at the University of New Mexico. Currently the collection numbers 20,000 mammals, 3000 birds, 7800 amphibians and reptiles, and 4600 catalogued lots of fishes. After 15 November, 1993, loan requests and inquiries should be made to Michael Bogan, Curator or Cindy Ramotnik, Collections Manager, at their new address: *National Biological Survey, Museum of Southwestern Biology, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA; Tel. (505) 766-3903.*

Southwestern Research Station Student Support Fund

The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona. Information and application forms for this program and other Museum grant programs can be obtained by writing: *Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024-5192, USA.* Application due date: 15 February 1994. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632, USA. Tel. (602) 558-2396.*

Guidelines For The Husbandry Of Amphibians And Reptiles

Specific guidelines for the husbandry of "typical" laboratory animals such as rats, mice, hamsters, and dogs, are set forth by the federal government (*Guide to the Care and Use of Laboratory Animals*, NIH publication 86-23). Such federal guidelines have not been extended to amphibians and reptiles, and, perhaps this is fortunate as the highly diverse requirements of these animals would confound attempts to create a standard husbandry. On the other hand, the policies of institutions, granting agencies, etc. require that researchers follow appropriate husbandry protocols and research procedures. For this reason, I would like to recommend several recent publications that should be extremely useful to both researchers and institutional animal care committees.

The following three publications are available free-of-charge from the Animal Welfare Information Center (you must provide formatted HD disks). Contact: *Animal Welfare Information Center, National Agricultural Library, 10301 Baltimore Boulevard, Beltsville, Maryland 20705, USA. Tel. (301) 504-5563 or (301) 504-6212).*

1) Berry, D. J., M. D. Kreger, J. L. Lyons-Carter. 1992. Information resources for reptiles, amphibians, fish, and cephalopods used in biomedical research. USDA, National Agricultural Library, Animal Welfare Information Center, Beltsville, Maryland, 87 pp. (This is a bibliography of the major publications on care and use of amphibians and reptiles in the laboratory setting.)

2) Fact Sheet: Electronic information products available from AWIC. I. Animal welfare legislation and policies: The animal welfare act, amendments, and regulations, and, II. Animal welfare recommendations and resources.

3) Pough, F. H. 1991. Recommendations for the care of amphibians and reptiles in academic institutions. National Academy Press, Washington, D.C., 21 pp. (This publication was written, in part, to educate non-herpetologists about the features of ectotherms critical to their care.)

4) Schaeffer, D. O., K. M. Kleinow, and L. Krulisch, (eds.). 1992. The Care and Use of Amphibians, Reptiles and Fish in Research. Scientists Center for Animal Welfare, Bethesda, Maryland, 196 pp. [This publication has a series of papers on husbandry, including cage design, anesthesia, euthanasia, and stress management. Available from *Scientists Center for Animal Welfare, 4805 St. Elmo Ave., Bethesda, Maryland 20814, USA. Tel (301) 654-6390, $40*].

MEETINGS

ASC/SPNHC Joint Meeting

The Association of Systematics Collections and the Society for the Preservation of Natural History Collections will have a joint meeting at the Missouri Botanical Garden 11-15 May 1994. The theme for the meeting is "Collections Planning and Policies." The meeting will include a joint workshop, a public policy review, SPNHC technical sessions and a training workshop. Program information and registration materials will be sent to members and included in upcoming issues of both the *ASC Newsletter* and the *SPNHC Newsletter*. For further information contact *ASC, 730 11th Street, NW, Second Floor, Washington, D.C. 20001, USA. Tel. (202) 347-2850.*

A Symposium On The Status And Conservation of Florida Turtles

This symposium will be held 2-3 April 1994 at Eckerd College, St. Petersburg, Florida. It is co-sponsored by the Gopher Tortoise Council, League of Environmental Educators in Florida, and Eckerd College.

Turtle conservation is an international effort. Florida, where ten percent of the world's turtle species are known to occur, is no exception. Over half of the 25 species that occur in Florida are in need of conservation attention. This symposium will address specific problems faced by Florida turtle species, as well as conservation strategies and potential solutions. This meeting will help to unite the previously separate efforts of marine turtle, tortoise, and freshwater turtle biologists. In addition to bringing together Florida turtle researchers, this two-day symposium will include representatives from the academic community, governmental agencies, conservation organizations, the environmental education community, and the outdoor/environmental writers' community for the benefit of Florida turtle conservation.

The League of Environmental Educators in Florida will be conducting an environmental education workshop during the symposium. The workshop will feature presentations by environmental educators actively involved in Florida turtle conservation.

For more information, or to be placed on our mailing list, please write to: *GTC c/o George Heinrich, P.O. Box 61301, St. Petersburg, Florida 33784-1301, USA*. Donations are needed to support this effort. Donations are tax-deductible and should be made payable to the Gopher Tortoise Council (earmarked for the Florida turtle symposium) and mailed to the same address.

British Herpetological Society Meetings For 1994

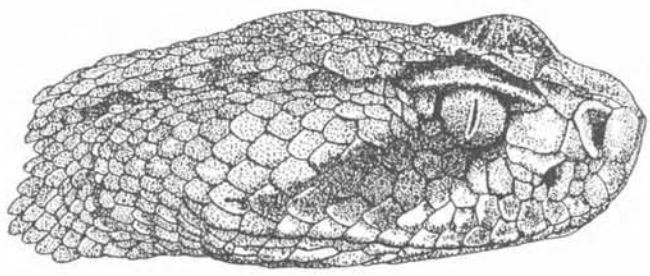
The following list provides dates, and in some cases, only preliminary details of meetings of the British Herpetological Society scheduled for 1994. Further details will follow in the *Bulletin* of the BHS.

February 5 - Herpetofauna Recorders' Meeting (HRM) 1994) (University of Manchester).

March 19 - Annual General Meeting (Birkbeck College London). Speakers will be Rob Quest (Heathrow Customs: "Reptile Imports"), Dr. Andy Smart (Bristol University: "Nesting success of green turtles at Kazanli, Turkey"), Dr. S. Hugh-Jones (Cambridge University: "Snakes, frogs, and other herps in northwest Amazonia").

May 1 - Joint Conservation & Education Committee Meeting.

May 7 - Captive Breeding Committee Amphibian Meeting (New Denham).



May 15 - "Leapers and Creepers" event, organized by Surrey Wildlife Trust, followed by visit to Beam Brook.

July 2 - Captive Breeding Committee Animal Husbandry workshop (New Denham).

October 15 - Autumn General Meeting (Birkbeck College London). Speakers will be Chris Wild (Nottingham: "The montane chameleons of the Cameroons Highlands"), Dr. Jim Foster (Durrell Institute of Conservation & Ecology: "Reptile conservation in south India"), Dr. Angelo Lambiris (Essex: "Southern African amphibians").

November 5 - Captive Breeding Committee Captive Stock Sale (New Denham).

December 3 - Research Committee Meeting (Birkbeck College, London).

Crotalus scutulatus. USA: Arizona: Pima Co., Avra Valley Rd. Illustration by Chuck Smith.

LEGISLATION & CONSERVATION ALERT

Call for information on the status of amphibians and reptiles.—This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered herps. We are in need of more information especially on the State and Province level. Please send pertinent information to the Section Editor.

USA: Department of the Interior: The National Biological Survey (NBS) was created 1 October 1993, by assembling portions of the biological research and survey elements of three Departmental bureaus—the U.S. Fish and Wildlife Service, the National Park Service, and the Bureau of Land Management. The NBS will not incorporate regulatory or resource management responsibilities. The NBS will use and establish scientific protocols in cooperation with other agencies to enhance comparability of reseach and long-term trend analyses. The inventory program will be conducted in concert with other federal and state agencies, The Nature Conservancy's Natural Heritage Programs, non-governmental organizations, and academia. (Department of the Interior news release, 26 April 1993).

USA: Arkansas: The Arkansas Department of Fish and Game has issued an Emergency Proclamation which prohibits the capture and possession of the alligator snapping turtle (*Macroclemys temmincki*). This emergency action was prompted by evidence of the decline and large scale commercial trade in this uniquely vulnerable stream-dwelling species. The trade was primarily in the export of turtle meat from the state. Regulations will be formulated within 120 days of the proclamation (4 October 1993) which will address the possession of captive animals. There are concerns that captive stock will be discarded in inappropriate habitats. Herpetologists and conservation biologists are encouraged to offer support in the formation of appropriate legislation. Contact: *Steve Wilson, Director, Arkansas Fish and Game, tel. (800) 364-4263.* This information was submitted by Steve D. Santhuff, *Macroclemys* Conservation Committee, Department of Zoology, University of Florida, Gainesville, Florida 32611, USA.

USA: Georgia: The Georgia Department of Natural Resources has updated its endangered species list and it now includes the following: Endangered: *Dermochelys coriacea, Eretmochelys imbricata, Lepidochelys kempii*; Threatened: *Caretta caretta, Chelonia mydas, Clemmys muhlenbergii, Drymarchon corais couperi, Gopherus polyphemus, Graptemys barbouri, Macroclemys temminckii*; Rare: *Graptemys geographica, G. pulchra, Ambystoma cingulatum, Amphiuma pholeter, Aneides aeneus, Cryptobranchus alleganiensis, Haideotriton wallacei, Notophthalmus perstriatus, Plethodon petraeus*; Unusual: *Clemmys guttata*. However, the DNR Board has limited the enforcement of the law to public lands owned by the State of Georgia. It also states that anyone charged with killing or harming a protected species must have shown intent to violate the act. Critics contend that these revisions have weakened the state's endangered species law. For more information contact: *Georgia Department of Natural Resources, 205 Butler Street, Suite 1252, Atlanta, Georgia 30334, USA.*

USA: Maryland: The Maryland Department of Natural Resources announced new regulations that affect the owners of all native reptiles and amphibians. Under the new regulations, an individual may possess up to four of each species of snake, lizard, salamander, or turtle and up to twenty-five of each frog, toad, or red-spotted newt without a permit. Any species listed by Maryland's endangered species law cannot be possessed. Bog (*Clemmys muhlenbergii*), wood (*C. insculpta*), and spotted turtles (*C. guttata*) may not be collected from the wild under these new regulations.

To possess more than the limits set forth, a permit ($25/yr) must be obtained. All animals above the limits must be of captive origin or purchased from a pet store; none may come from the wild. The permit allows for the captive breeding and commercial sale of captively produced animals. Pet stores must have a permit to sell herps considered native to Maryland and all animals must have come from captive breeding or been legally obtained from out of state. For a copy of the new regulations or to apply for a permit contact: *Permits Coordinator, Wildlife Division, Department of Natural Resources, Tawes State Office Building, E-1, Annapolis, Maryland 21401, USA.*

CITES Amendment: The Convention on International Trade in Endangered Species (CITES) is a treaty designed to control international trade in certain animal and plant species that are, or may become threatened with extinction. Appendix I contains species threatened with extinction that are, or may be affected by international trade; Appendix II includes species that may become threatened if their trade is not brought under control; Appendix III includes species that individual CITES Parties identify as subject to domestic regulations for the purpose of restricting or preventing exploitation. The wood turtle (*Clemmys insculpta*) has been added to Appendix II and the bog turtle (*Clemmys muhlenbergii*) has been moved from Appendix II to Appendix I (*Endangered Species Technical Bulletin*, Vol. XVIII No. 1, 1993).

KURT A. BUHLMANN
SSAR Conservation Committee.

REGIONAL SOCIETIES

New Herpetological Societies

Please note and add the following new regional herpetological societies to your directories:

Dragon Patch Herpetology Club
913 East Main Street
Salem, Virginia 24513, USA

Tennessee Valley Herpetological Society
P.O. Box 360
Ooltewah, Tennessee 37363, USA

Society Address Changes

Please note the following changes of address:

Lubbock Turtle and Tortoise Society
2295-G Chambers Road, #157
Aurora, Colorado 80011-3204, USA

Rocky Mountain Herpetological Society
c/o Charles Sarkisian
5362 North Nevada Avenue, Apt. 201
Colorado Springs, Colorado 80918-8621, USA

In addition, if anyone knows of current addresses for the following societies, please forward them to the Regional Societies Section Editor: Central Kentucky Herpetological Society, Endangered Turtle Protection Foundation, Upstate Herpetological Association.

ARTICLES

Intraspecific Oophagy In Reptiles

Reptilian behavior has been the subject of voluminous reviews which summarize the abundant anecdotal literature. For instance, Carpenter and Ferguson (1977) reviewed the massive literature on mating, courtship, aggression, and social communication. Greene (1988) reviewed antipredator behaviors. Somma (1990) reviewed parental care. Published reports on oophagy range from brief notes of its occurrence to full descriptions of the behavior. In this paper we provide an updated review of the literature on oophagy in reptiles, a review of the hypotheses proposed to account for this behavior, and suggestions for reporting future observations.

Oophagy (technophagy – Hamilton 1958; prolicide – Auffenberg 1981; cannibalism – Heimlich and Heimlich 1947; Martof 1956; Fitch and Henderson 1978; Christian and Tracy 1982) has been used to refer to two different behavioral acts: 1) predation of the eggs of other vertebrate species by, for example, *Dasypeltis* of Africa (Gans 1952) and *Pituophis melanoleucus* in North America (Wright and Wright 1957) (interspecific oophagy), and 2) consumption of a female's own eggs, embryos, or extraembryonic membranes, or the consumption of the eggs of a conspecific female by other females or by males (intraspecific oophagy). The published literature reflects these two definitions.

The following list catalogs published and unpublished observations of intraspecific oophagy known to us through 1992. Details are provided when available to differentiate between consumption of the individual's own eggs and the consumption of them by a conspecific. Additional information is included if pertinent. Some of the reports noted only that the behavior occurred in the species; these are indicated as "captive" or "field" observations to distinguish between these two environments. A primary aim of this review is to stimulate additional reports of such behavior so that a more complete database is available for analyses of causes and benefits. Higher order taxonomy follows Zug (1993). Observations by us are noted by our initials.

Lacertilia

Anguidae: *Elgaria coerulea* – Females ate extraembryonic membranes (J. R. Stewart *in* Guillette and Hotton 1986; Somma 1990). *Gerrhonotus liocephalus* – A nest-guarding female apparently removed spoiled eggs from the nest (H. W. Greene *in* Tinkle and Gibbons 1977). *Ophisaurus attenuatus* – Brooding females sometimes eat their own eggs (Fitch 1970, 1989). A captive female consumed her own freshly-laid eggs (Vogt 1981). *Ophisaurus ventralis* – A field-collected specimen contained two conspecific eggs (Hamilton and Pollack 1961). A captive female consumed her entire clutch (Villiard 1969).

Gekkonidae: *Ailuronyx seychellensis* – captive (Slavens 1987). *Cosymbotus platyurus* – field (Church 1962). *Gehyra mutilata* – field (Church 1962). *Gekko petricolus* – Zaworski (1987) observed captive females consume infertile eggs and empty eggshells. *Hemidactylus brookii* – Bustard (1957) observed a male eating eggs of conspecific females in captivity. *Hemidactylus frenatus* – captive (Miller 1979); field (Church 1962). *Hemidactylus turcicus* – Captive females guarding their eggs were "overpowered" by conspecifics who ate their eggs (L. A. Somma, pers. comm.). *Lepidodactylus lugubris* – captivity (Miller 1979). JDG observed a wild female on Guam eat two eggs after she was disturbed. *Phelsuma dubia, P. laticauda,* and *P. madagascariensis* – Captive females of these species will eat empty egg shells after neonates hatch, ingest inviable eggs, and consume freshly-laid eggs when their diet is deficient in calcium (Osadnik 1984). *Phelsuma sundbergi* – One wild-caught individual contained an egg shell, "probably gecko," in its stomach (Evans and Evans 1980). *Ptychozoon kuhli* – captivity (JDG). *Ptyodactylus hasselquistii* – One egg was found in a wild-caught female (Perry and Brandeis 1992).

Helodermatidae: *Heloderma horridum* – captive (R. E. Honegger, pers. comm.; JDG). *Heloderma suspectum* – captive (R. E. Honegger, pers. comm.; JDG).

Iguanidae: *Anolis equestris* – A male dug up and ate the eggs of a female with which he had mated (Miller 1979). *Conolophus pallidus* – Field observation of a female eating eggs of conspecifics (Christian and Tracy 1982). *Conolophus subcristatus* – Captive males ate eggs of conspecific females (H. K. Snell, pers. comm.). *Ctenosaura similis* – field (Fitch and Henderson 1978).

Lacertidae: *Lacerta agilis* – Darevsky (1946) described oophagy by captive males. *Lacerta lepida* – captivity (Laferrere 1970). *Lacerta viridis* – captivity (Street 1979).

Scincidae: *Corucia zebrata* – Captive females ate extraembryonic membranes of their offspring (Honegger 1985; Wright 1991). Consumption of extraembryonic membranes was observed on several occasions at the Philadelphia Zoo (JDG). *Egernia cunninghami* – Females ate extraembryonic membranes (Niekisch 1975, 1980). *Eumeces anthracinus* – A captive female ate four of her eight eggs (Hamilton 1958). *Eumeces callicephalus* – An egg of a captive female was eaten by her or a conspecific cagemate (Zweifel 1962). *Eumeces egregius* – A captive female *E. e. onocrepis* ate one of her four eggs and a captive female *E. e. insularis* ate all five infertile eggs (L. A. Somma, pers. comm.). *Eumeces fasciatus* – One of 25 females consumed all of her eggs after being brought into captivity (Cagle 1940). A captive female consumed two of her own eggs (McCauley 1945). Fitch (1954) found two eggs in field-collected females. Groves (1982) described the oophagic behavior of this species and found that 20 of 21 eggs were eaten by their attendant captive females; the last egg was eaten by a conspecific female. Vitt and Cooper (1986) observed ingestion of both dead and live eggs by captive females but gave no data. *Eumeces inexpectatus* – A field-collected female contained one of her own eggs in her stomach (Hamilton 1958). Vitt and Cooper (1986) observed ingestion of both dead and live eggs by captive females but provided no specifics. A captive female ate an infertile egg of a clutch she was brooding (L. A. Somma, pers. comm.). *Eumeces laticeps* – A female brooding 15 eggs consumed twelve of them after being placed in a terrarium (Martof 1956). Among 15 females with broods in the laboratory, seven ate 1-3 of their own eggs and three consumed their entire clutches (Vitt and Cooper 1985). These authors also provided circumstantial evidence that a wild female consumed two of her 12 eggs in a nine day period. *Eumeces obsoletus* – A captive female consumed her own eggs (Burt 1928). *Eumeces okadae* – 19 of 272 eggs in natural nests were eaten by the attending females (Hasegawa 1985). *Eumeces septentrionalis* – Frequently-fed, captive females consumed their inviable eggs (Somma 1989a,b). *Eumeces skiltonianus* – Tanner (1957) provided circumstantial evidence that a wild female had consumed one of her eggs. *Leiolopisma otagense* – Females ate extraembryonic membranes (Smithells *in* Sharrell 1966). *Leiolopisma smithii* – Females ate extraembryonic membranes (Somma 1990). *Mabuya capensis* – Females were observed eating extraembryonic membranes (FitzSimons 1943; Rose 1929, 1950). *Mabuya macrorhyncha* – A captive female ate the extraembryonic membranes of her neonates (Reboucas-Spieker and Vanzolini 1978). *Scincella lateralis* – Captive females were frequently observed to eat eggs of conspecifics (L. A. Somma, pers. comm.). *Sphenomorphus quoyii* – Females tore extraembryonic membranes and presumably swallowed them (Shine 1988). *Tiliqua (Trachydosaurus) rugosa* – Captive females ate the extraembryonic membranes of their neonates (Hitz 1983; Mertens 1960).

Teiidae: *Ameiva corvina* – A captive female was observed carrying a slit and flaccid egg in her mouth (JCM). *Cnemidophorus sexlineatus* – A captive female dug up and ate two eggs of a conspecific (L. A. Somma, pers. comm.). *Cnemidophorus tesselatus* – Captive females were observed to dig up and eat eggs of

conspecifics (L. A. Somma, pers. comm.). *Cnemidophorus uniparens* – On three occasions conspecifics consumed eggs of cagemates (Crews et al. 1983).

Varanidae: *Varanus bengalensis* – Deraniyagala (1953) mentioned this species eats the eggs of conspecifics. A male ingested eggs during two breeding seasons in captivity (W. Auffenberg *in* Slavens 1982). *Varanus exanthematicus* – Cissé (1972) found conspecific eggs in the stomach of a single field-collected specimen. *Varanus indicus* – 20 eggs of a female collected on Guam were ingested by a male or the female or both in captivity (JDG). *Varanus komodoensis* – Captive adult females ate eggs of conspecifics (Lederer 1942). Auffenberg (1981) observed this behavior in captive adult males. Other reports of oophagy in captives are in Brongersma (1932), Oesman (1967), and Galstaun (1973). *Varanus prasinus* – One of four eggs laid in captivity was eaten by an adult male (J. B. Murphy, pers. comm.). *Varanus salvator* – Captive males and females have been recorded eating conspecific eggs (R. E. Honegger, pers. comm.). A captive female consumed one of her own eggs at the Philadelphia Zoo (JDG).

Xantusiidae: *Xantusia henshawi* – A captive female ate the extraembryonic membranes of her neonate (Shaw 1949). *Xantusia vigilis* – Females ate extraembryonic membranes in captivity (Cowles 1944; Miller 1954).

Serpentes

Boidae: *Corallus enydris* – Captive females ate their own eggs after deposition (Jes 1984; Miller 1983). *Epicrates cenchria* – A captive female ate an undeveloped ovum (Boos 1976). A captive female ingested a dead neonate and its foetal membrane after nudging it with her snout (Groves 1981). *Epicrates striatus* – Captive females ate dead neonates and their membranes (Hanlon 1964; Huff 1980; Slavens 1987). Captive females have been observed to eat undeveloped ova, extraembryonic membranes, and dead neonates (Groves 1981). *Eryx colubrinus* – captive (Ross and Marzec 1990). *Eunectes murinus* – Neill and Allen (1962) described the feeding behavior of a captive female which ate 15 of 19 aborted embryos; the four live-born neonates were not eaten. Holstrom and Behler (1981) described the ingestion of extraembryonic membranes and an undeveloped egg in captive females. *Eunectes notaeus* – Captive females have been observed to eat infertile eggs (Holmstrom 1981; Slavens 1985, 1988; Townson 1985).

Colubridae: *Ahaetulla nasuta* – captive (Reippel 1970). *Cemophora coccinea* – Ditmars (1907) observed a captive female consume seven of eight eggs containing near-term embryos. Palmer and Tregembo (1970) observed one captive female swallow three eggs laid by a conspecific. *Elaphe scalaris* – captive (Leferrere 1970). *Heterodon nasicus* – captive (M. J. Kowak, pers. comm.). A captive female ate several of her own eggs on two separate occasions (Hammack 1991). *Lampropeltis triangulum* – An entire clutch was eaten by the resident captive male (J. B. Murphy, pers. comm.). A captive female was observed to regurgitate one of her eggs (Groves and Sachs 1973). *Leptodiera annulata* – A captive female consumed her entire clutch (Wehekind 1955). *Oligodon taeniolatus* – A recently captured female ate three eggs less than one hour after laying them (Minton and Anderson 1963).

Elapidae: *Naja naja* – Oophagy was presumed to occur based on Hindu scriptures dating to 600 B.C. (Rao 1957).

Pythonidae: *Python molurus* – A female was observed removing infertile or undeveloped ova from her clutch (Griehl 1984).

Viperidae: *Agkistrodon bilineatus* – A captive female ingested two dead neonates (and their extraembryonic membranes) of her own litter (JDG).

Testudines

Emydidae: *Clemmys muhlenbergii* – captive (Robotham 1963). Arndt (1977) noted that a captive female ate one of her own eggs after oviposition. *Terrapene carolina* – captive (Ernst and Barbour 1972; W. B. Love, pers. comm.).

Testudinidae: *Gopherus agassizii* – A captive female dug up and ate the eggs of a conspecific who had just completed nesting (Nichols 1953).

Crocodylia

Alligatoridae: *Alligator mississippiensis* – field (Kushlan and Simon 1981). Kellogg (1929) recorded three partially digested eggs in the stomach of a Louisiana specimen.

Crocodylidae: *Crocodylus niloticus* – Females were observed to pick up and eat eggs from nests, egg fragments were found in feces, and stomachs of several females killed contained eggs (Modha 1967; Welman and Worthington 1943). Cott (1961) found 87 conspecific eggs in the stomach of one individual.

Discussion

Intraspecific oophagy has been reported to occur in 58 species of lizards, 16 snakes, three turtles, and two crocodilians. In lizards, 59 observations (number of literature and personal observation records) occurred in captivity and 15 in the field, whereas all observations of snake and turtle oophagy were of captive specimens.

Oophagy is a specialized behavior not involving the active killing of another conspecific or consumption of carrion. Consumption of unhatched, late-term embryos might be considered cannibalism, but unhatched juveniles are unable to utilize defensive behaviors, whereas newly hatched neonates and those newly freed from embryonic membranes may possess innate defensive strategies, or visual or other cues that modify the predatory behavior of adult conspecifics. The hatching event is an adequate distinction between when the behavior should be called cannibalism or oophagy.

Intraspecific oophagy is probably a form of parental care when performed by females on their own eggs. Several hypotheses have been proposed to explain the causes of this behavior in brooding females.

Hunger/thirst hypothesis: Oophagy by the parental female may be caused by hunger (Cagle 1940) or a combination of hunger and thirst (Vitt and Cooper 1986). Fitch (1954) thought this behavior occurred in order to satisfy hunger without the female having to leave the nest.

Mistaken food hypothesis: Decomposing eggs may have a different odor than healthy eggs and females may mistake them for prey items (R. B. Huey *in* Shine 1988 p. 292).

Hygiene hypothesis: Oophagy by the brooding female may minimize the transfer of bacteria, fungi, and other harmful microorganisms from dead or infected eggs to viable eggs (Groves 1981, 1982; Shine 1988; Somma 1989, 1990; Tinkle and Gibbons 1977).

Predator avoidance hypothesis: Consumption of dead eggs by the female may reduce detection of the nest and attendant female by predators, presumably because of chemical cues released by rotting eggs and aborted ova (Groves 1982; Neill and Allen 1962; Somma 1990; Tinkle and Gibbons 1977).

Captive females of several species of *Phelsuma* ingested their own eggs after they were damaged experimentally, and when these animals were kept on a calcium deficient diet, they ate their eggs immediately after laying them (Osadnik 1984). Brooding captive female *Eumeces septentrionalis* will ingest mechanically killed or introduced rotten eggs and eggs swabbed with the contents of a rotten egg (Somma 1989). Brooding female *Eumeces fasciatus* will eat rotting eggs, even after consumption of insect prey (Groves 1982). These observations suggest that the hygiene and predator avoidance hypotheses may explain the causes of oophagy in brooding females of some species. However, dietary deficiencies may cause oophagy in other species. Data are lacking to more completely differentiate among the existing hypotheses. Oophagic behavior in brooding females may have multiple causes.

In addition to being a form of parental care, intraspecific oophagy is a form of predation when performed by conspecifics.

Hypotheses advanced to explain the causes of infanticide (Huntingford and Turner 1987) may also apply to the causes of oophagy. These are, as modified from Jenssen et al. (1989), (1) exploitation of eggs and aborted neonates in egg membranes as food, (2) elimination of potential population members as competitors for limited resources, (3) improved breeding opportunities for conspecific predators by removing non-related offspring in the embryo stage from prospective mates, and (4) improved inclusive fitness of parents by their selective killing of non-related offspring. In addition, intraspecific oophagy may be a method of density–dependent population regulation, as suggested for some cannibalistic lizards (Badir 1968; Jenssen et al. 1989; Mitchell 1986). None of the observations listed above, however, allows us to distinguish among these potential causes of oophagy by conspecifics.

Observations of oophagic behavior should be reported, but they should contain the circumstances within which the behaviors were performed, if they occurred in the field or in captivity, and whether a single individual (e.g., female parent) or a conspecific was involved. Consistent information and experiments on a variety of species could provide insights into the causes and benefits of these behaviors.

Acknowledgments.—We are grateful to the libraries and the librarians of the University of Richmond, Smithsonian Institution, University of Tennessee, and Virginia Commonwealth University for their assistance. Katherine E. R. Smith and Betty B. Tobias of the University of Richmond were particularly helpful and were able to locate the most obscure references.

Original observations were contributed by D. G. Broadley, R. E. Honegger, M. J. Kowak, W. B. Love, M. J. Miller, and H. K. Snell. I. S. Darevsky, H. W. Greene, R. E. Honegger, J. B. Murphy, G. R. Zug, and R. G. Zweifel assisted with literature sources. A. M. Bauer, H. A. Dundee, K. Hatch, W. W. Lamar, J. B. Murphy, L. A. Somma and J. Stein reviewed drafts of the manuscript and kindly provided additional observations and literature records.

REPTILES AND AMPHIBIANS OF CHEYENNE BOTTOMS

Joseph T. Collins
Suzanne L. Collins

In the Western Hemisphere, Cheyenne Bottoms, a 19,857 acre marsh located in Barton County in central Kansas is famous as a way station for migrating waterfowl, but not much attention is given to the variety of amphibians and reptiles that call the Bottoms their home.

Joe Collins, author of fifteen wildlife books, and Suzanne Collins, a noted wildlife photographer, have combined talents to produce a field guide with stunning color photos and descriptions of these fascinating and misunderstood creatures that live in this important wetland.

This book, which initiates a series on the natural history of Cheyenne Bottoms, is the result of studies sponsored by the U.S. Fish & Wildlife Service, Western Resources, Inc., The University of Kansas Museum of Natural History, Kansas Department of Wildlife and Parks, and the Kansas Herpetological Society.

Observations Of Autohemorrhaging In *Tropidophis haetianus, Rhinocheilus lecontei, Heterodon platyrhinos,* And *Nerodia erythrogaster*

In a recent review of reptilian defense mechanisms, Greene (1988) noted the occurrence of ocular hemorrhage commonly observed in *Phrynosoma* spp. and cited an observation of nasal and oral hemorrhage in *Tropidophis pardalis* (Hecht et al. 1955). In this note we present original observations of autohemorrhage in *Tropidophis haetianus*, *Rhinocheilus lecontei*, *Heterodon platyrhinos*, and *Nerodia erythrogaster*, and review the literature concerning autohemorrhage in snakes.

Dwarf boas of the genus *Tropidophis* have often been observed to respond to capture or handling with autohemorrhage in the vicinity of the eyes, mouth, and/or nose. This behavior has been noted in *T. greenwayi* (Iverson 1986), *T. maculatus* (Campbell 1951; Underwood 1952), *T. melanurus* (Mertens 1946; Stull 1928), *T. pardalis* (Hecht et al. 1955; Petzold 1969), *T. parkeri* (Campbell 1951), *T. paucisquamis* (Carvalho 1951), and *T. semicinctus* (Darlington 1927). On 5 March 1990 we collected a female *T. haetianus* (SVL 554 mm) (Bobby Witcher Memorial Collection, Avila College BWMC 4174) from under a rock beside a stream 6.1 km W of the junction of highways (Hwy) 44 and 46, along Hwy 46, Provincia de Barahona, República Dominicana. This specimen was placed in a collecting bag immediately after capture. Upon removal, some 10 min later, it was coiled in a tight ball and began bleeding profusely from the mouth and both eyes. An estimated 6-8 large drops of blood were expressed before the snake was returned to the sack where it continued to bleed for several minutes. No musk was exuded.

On 8 March 1990 another female (SVL 440 mm) was captured, again under a rock beside a stream, on the south edge of Paraiso, Provincia de Barahona. This snake responded similarly to the first by coiling into a tight ball. After a few minutes of further rock turning while the snake was still held in one hand, the collector noticed his hand was smeared with blood. A large drop was observed on the left side of the face of the snake, along the line of the mouth. No further bleeding was observed with handling on subsequent days.

During a field trip to the Provincia de Barahona during June 1991, simultaneous oral and ocular bleeding was observed in three of four captured *T. haetianus*. The behavior was observed in both males and juveniles of the species.

Cloacal hemorrhage has been noted in *Rhinocheilus l. lecontei* (Hanley 1943), and observed in 7 of 27 (26%) *R. l. tesselatus* taken in Eddy Co., New Mexico, and Culberson and Hudspeth Counties, Texas (McCoy and Gehlbach 1967). McCoy and Gehlbach also recorded cloacal hemorrhage in four other specimens of *R. l. tesselatus* and one incidence of nasal hemorrhage (epistaxis) in snakes from western Texas and Coahuila, México. They concluded that hemorrhaging may be confined to females of this

species, and that epistaxis is observed less commonly than cloacal hemorrhage. We here report cloacal hemorrhage in a female *R. l. tesselatus* (SVL 470 mm) (BWMC 1251) taken in Clark Co., Kansas, and 4 of 10 *R. l. lecontei* taken in Clark and Nye Counties., Nevada.

The Kansas specimen was found on 21 April 1979, under a rock on a dry hillside, 24.1 km N of Ashland at ca. 1400 h. Prior to any attempt to pick it up, the snake began writhing and expressing blood from the cloaca. No oral or nasal bleeding was observed. During subsequent handling the specimen went limp and bleeding stopped. On the assumption that the snake may have been injured, it was monitored carefully for several weeks in captivity, during which time it behaved normally and consumed two lizards.

The four specimens from Nevada were all taken on the road at night, between 31 May 1970 and 13 August 1973. One individual exhibited oral and cloacal bleeding. Of the four, it reacted most violently with much writhing, and production of considerable quantities of musk. Two of these specimens (both females) were preserved (KU 176894, LACM 133966). The other two were released without determination of sex.

Platt (1969) noted that snakes of the genus *Heterodon* sometimes exhibit oral hemorrhaging during the death-feigning (letisimulation) phase of defensive behavior. We have observed cloacal hemorrhaging twice in specimens of *Heterodon p. platyrhinos* from Missouri. The first occurrence was not associated with letisimulation. On 18 August 1978 a male (SVL 489) (BWMC 1022) was collected crossing a road at ca. 0600 h in eastern Jackson Co. When grasped, the snake coiled quickly and produced two or three drops of blood from the cloaca. It rapidly calmed, at which time the bleeding stopped. It did not release any musk. The specimen was maintained alive for several months before preservation.

On 16 June 1984 at ca. 2100 h, the second *H. p. platyrhinos* was observed crossing a gravel road, 12.8 km NE of Climax Springs, Camden Co. When grasped, the snake first writhed, forcefully exuded several large drops of blood from its vent accompanied with the sound of escaping flatus, and after a few seconds went limp in the collector's hand, apparently feigning death. There were no apparent signs of trauma other than the rather considerable bleeding. This specimen was released near the site of capture, and was gone the next morning.

To our knowledge autohemorrhage has never been reported in snakes of the genus *Nerodia*. On 26 March 1991 a male *Nerodia erythrogaster transversa* (SVL 604 mm) was collected in Cherokee Co., Oklahoma. When grabbed it thrashed wildly, defecating, and squirting musk from its cloacal glands. As the head was grasped the snake opened its mouth and several drops of blood oozed from the gums of the lower jaw.

McCoy and Gehlbach (1967) point out (in *Rhinocheilus*) that although autohemorrhage in snakes is often associated with defensive behavior, it is difficult to attribute operational defensive function to the bleeding. Frye (1981) indicates the causes of hemorrhage in reptiles are the same as those in higher vertebrates, and that spontaneous extravasation can result from a relative or absolute deficiency of thrombocytes. Spontaneous nasal bleeding is not an uncommon occurrence in young thoroughbred horses during extreme physical exertion (Kelly 1974) and it is possible both oral and cloacal autohemorrhage of the colubrids described here is similarly "exertion-related." In almost all cases, bleeding is subsequent to bouts of thrashing, writhing, or rapid coiling.

The autohemorrhaging observed in *Tropidophis* spp., however, may represent a different phenomenon. It differs from that observed in colubrids by being preceded, generally, by the described "balling" behavior, and by the presence of repeatedly observed nasal and orbital bleeding. This indicates more extensive involvement than that of superficial vessels of the oral or cloacal mucosae. Indeed the source of orbital bleeding could be the sinus orbitalis as associated with orbital blood spurting in *Phrynosoma* (Burleson 1942), although in *Tropidophis* the blood simply flows across the eye under the ocular and is not forcefully ejected. Still, it is difficult to assign defensive significance to this behavior. Until a defensive mechanism can be attributed to autohemorrhaging, at least in snakes, it seems prudent to consider it a physiological by-product of increased blood pressure associated with sudden and violent exertion and/or a "fright, fight, or flight" behavioral response.

Acknowledgments.—We thank Carol Cunningham and Scott Maxey for making and contributing some of the above observations.

Sexual Selection: What Has Been Learned From Ectotherms? Quite A Lot!

Darwin was greatly impressed by behavioral and morphological characters in animals that appear to play no role in the "struggle for existence." Because such characters could not be explained as products of evolution by natural selection, Darwin formulated his theory of sexual selection to account for them. For Darwin, sexually selected traits provide an advantage to their bearers solely in relation to the "struggle to reproduce." He easily explained the evolution of such characters as fighting behavior and the possession of weapons, usually in males, as aiding their bearer in direct competition for females. However, the evolution of other traits, usually limited to males but not involved in direct competition, caused Darwin some trouble. By positing an aesthetic sense in females, Darwin explained such characters as vocalizations and bright, gaudy colors as being advantageous because they are attractive to and preferred by females.

Darwin was clearly aware of characters in fishes, amphibians, and reptiles that appear to have evolved by sexual selection for he devoted a whole chapter to these animals (chapter 12 of Darwin 1871). However, Darwin could never have foreseen the great theoretical and empirical advances that have been made in the study of sexual selection, most especially within the last 20 years or so (reviewed in Bateson 1983; Bradbury and Andersson 1987; Cronin 1991; Harvey and Bradbury 1991; Halliday 1992). A symposium entitled "Sexual selection: what has been learned from ectotherms?" was held at the 1993 Joint Meetings of the American Society of Ichthyologists and Herpetologists, the Herpetologists' League, The Annual Larval Fish Conference, and the American Elasmobranch Society, convened at the University of Texas at Austin (27 May – 2 June 1993). The goal of the symposium organizers, Michael J. Ryan (Univ. of Texas, Austin) and A. Stanley Rand (Smithsonian Tropical Research Institute, Panama) was to summarize our current understanding of sexual selection in "lower vertebrates," and to highlight promising avenues for future research.

The symposium consisted of 29 papers presented by authors from five countries. In terms of taxonomic scope, 11 papers considered fishes, 10 anurans, and six reptiles. Only two papers dealt with salamanders, and only one was devoted to snakes. My aim in this paper is to make available a report of the proceedings of the symposium, based largely on personal notes and abstracts. Instead of discussing individual papers in the same order as they were presented (by Class), I have chosen to order them more-or-less in conceptual terms. I hope this report will be of use to herpetologists interested in sexual selection, especially those who were unable to attend the Meetings.

The last ten or so years have seen spectacular advances in theoretical studies of sexual selection. This is especially true concerning the evolution of mate choice, where debate still rages over the extent to which females obtain benefits (for themselves or their offspring) by being choosy (Kirkpatrick and Ryan 1991). The symposium began with a theoretical overview presented by M. Kirkpatrick (Univ. of Texas, Austin), who then went on to consider the extent to which empirical studies of ectotherms have enabled us to test theories and models of sexual selection. He concluded that, until recently, data and theory have coexisted rather than interacted in a somewhat uneasy sympatry. However, ingenuity in recent experimental designs and refinements/advances in theories and models cause Kirkpatrick to be optimistic about a true marriage of data and theory in the near future.

One area in which studies of lower vertebrates are actually stimulating new theoretical development concerns the evolutionary origins of male traits preferred by females. Ryan (1990) suggested that males might evolve certain sexual traits because of pre-existing biases in female sensory systems. For example, if females are especially sensitive to the color red (perhaps because they feed on red prey), then this sensory bias in the visual system may drive the evolution of red-colored sexual signals in males. A number of papers were presented at the symposium providing evidence for the evolution of male sexual traits through sensory exploitation of pre-existing biases in females.

A. L. Basolo (Univ. of California, Santa Barbara) reported that, in the platyfish and swordtails, the absence of a sword in males is the ancestral state (the sword is formed by modification of the anal fin and looks like, well, a sword!). When Basolo attached artificial swords to males of species that do not naturally have them, she found that females of these naturally-swordless species nevertheless preferred conspecific males with swords. This suggests that a pre-existing bias in females may have favored the evolution of swords, the bias arising before the sword itself. Put another way, a bias leading to a preference apparently predated the evolution of the preferred trait.

Female sailfin mollies prefer larger males as mates, although it is not clear how this preference evolved. To address this question, C. A. Marler and M. J. Ryan (Univ. of Texas, Austin) studied a related species, the Amazon molly. This is an "all-female" hybrid species which reproduces clonally, but requires sperm from heterospecific males for egg activation. In the Amazon molly, males make no genetic contribution to offspring and provide females with no material resources, and so female mate choice would not be expected under conventional sexual selection theory. However, female Amazon mollies prefer larger heterospecific males as "egg activators," a finding which suggests that a preference for larger males may simply be an ancestral trait that need serve no current function in any molly species.

Female preference for larger males also occurs in pygmy swordtails, to the extent that preferred males may be larger than those typically found in natural populations. Indeed, females may prefer large, heterospecific males over normal-sized conspecifics! However, M. R. Morris and M. J. Ryan (Univ. of Texas, Austin) have now located one natural population of pygmy swordtails in which males are abnormally large. Unexpectedly, they found that females from this population did not show a preference for larger male partners. Morris and Ryan suggest that a preference for large males may be a primitive character in the genus *Xiphophorus*, and that it appears to have been secondarily lost in some populations of pygmy swordtails.

Frogs of the *Physalaemus pustulosus* species group have provided some of the best evidence that male traits may evolve to exploit pre-existing sensory biases in females, as reviewed by M. J. Ryan and A. S. Rand. Males of different species produce rather different calls from one another; differences include details of temporal structure as well as the presence/absence of certain acoustic elements. In all cases there are species in which females prefer call parameters that are not present in the calls of conspecific males! By mapping female preferences and male traits onto an independent phylogeny for this species group, Ryan and Rand concluded that male calls apparently have evolved to exploit pre-existing biases in the female's auditory system. However, the exact form taken by male calls in any one species seems to be determined by constraints arising from the structure of the male larynx.

Unfortunately, W. E. Wagner, Jr. (Univ. of California, Santa Barbara) was unable to attend the symposium. However, his abstract reports that males may sometimes be able to exploit female sensory biases by altering sexual signals on a moment-by-moment basis. In Blanchard's cricket frog, females prefer males with deep-pitched calls. An individual male can alter the pitch of his call to make it sound more attractive, but by doing this he decreases his call's "active space." So, although males can alter their calls to make themselves more attractive (perhaps exploiting

a pre-existing sensory bias in females), they do so at the cost of being detected by fewer potential mates.

The manner in which the environment either facilitates or attenuates the transmission of a signal is an important factor affecting the evolution of sexual signals in many animals (Endler 1992). L. J. Fleishman (Union College) and E. R. Loew (Cornell Univ.) reported that habitat structure apparently has influenced the evolution of visual displays in anoline lizards. They examined the visual systems and display behaviors of five *Anolis* species occupying different habitats in Puerto Rico. In terms of visual systems, the species appear very similar. However, dewlap colors of males vary among the species. Fleishman and Loew showed that these differences in dewlap color seem to have evolved primarily in response to habitat-generated differences in dewlap visibility. If females prefer one kind of dewlap over another, it may simply be because certain kinds of dewlap are more easily seen than others.

Why female choice should evolve and be maintained when females obtain nothing from males except sperm has long been a puzzle. One way of determining whether such choice results in a direct benefit for females is to replace chosen males with others and then monitor female reproductive success. R. R. Warner (Univ. of California, Santa Barbara) performed just such an experiment on bluehead wrasse. He reported that some, but not all, females changed mating sites if their chosen males were replaced. Female fecundity was actually lower for choosy females than for non-choosy females, and remained lower even if the choosy females shifted mating sites after the replacement of preferred males! This result suggests that choosiness is disadvantageous for female bluehead wrasse, at least in terms of egg production, and provides a clear warning that we cannot simply assume that choosy females enjoy higher reproductive success.

Choosing males that are physiologically/metabolically superior may be advantageous to females if their offspring inherit superior genes from their fathers. R. Borowsky (New York Univ.) reported that, in the platyfish *Xiphophorus variatus*, alleles for superior physiology also affect pigmentation, and that these alleles vary geographically in response to habitat diversity. Borowsky argued that such a system is ideal for studying the evolution of female choice. If pigmentation reliably signals physiological vigor, and if the latter is heritable, the platyfish may provide a fine example of a system in which a "superficial" character correlated with a selected character could be captured by sexual selection, especially if the environment changes.

Guppies are excellent subjects for testing models of sexual selection. Many studies have shown that females choose males on the basis of the size and color of their spot patterns. As discussed by A. E. Houde (Lake Forest College), a male's "spottiness" may be at least partly dependent on his health and vigor, and so females may obtain good genes for their offspring by mating with spotty males. Houde also demonstrated that patterns of preferences differ among guppy populations in a manner correlated with the expression of spot colors in males; female preferences for spotty males are strongest for populations with the spottiest males. Although the latter result suggests that there may be a genetic correlation between male traits and female preferences in guppies, F. Breden (Univ. of Missouri, Columbia) reminded us that other studies of these fishes, such as mass selection on attractive males, have failed to find support for such a genetic correlation. Clearly, more work is needed.

Guppy sex is made even more complex (and interesting) by the fact that certain experiential factors may modify female mate choice. For example, L. A. Dugatkin (Univ. of Kentucky) reported experiments in which female guppies that were allowed to observe mate preferences in other females copied the choices of these others. The effect of copying was so strong that females observing the mate choices of others would reverse their own previous mate preferences! Another paper, not included in the symposium but highly relevant to this issue, reported that female guppies reared with individuals from other populations show a clear effect of previous exposure on female mate choice after maturity (A. L. S. Schubert and F. Breden, Univ. of Missouri, Columbia). A clear challenge is for quantitative geneticists to develop models of sexual selection that fully incorporate such experiential effects on mate choice.

Another fish that has been instrumental in deepening our understanding of sexual selection is the humble stickleback. As discussed by D. A. McLennan (Royal Ontario Museum), most attention has focused on female responses to male traits in these fishes, both behavioral and morphological (especially color). However, careful observation has shown that females also broadcast sexual signals to males during courtship. In particular, female color pattern conveys information to males concerning species identity, sex, and willingness to mate. This sets the scene for male mate choice. McLennan suggested that the courtship of sticklebacks should be described as an intersexual "dialogue" rather than a male-centered "monologue."

Many of the behavior patterns exhibited by breeding males involve considerable energetic expenditure. This is especially true in the many frogs and toads in which males produce vocalizations to attract females and repulse same-sex rivals. Energetic costs are of great importance if they negatively affect a male's ability to acquire mates (Pough et al. 1992). As discussed by C. C. Robb and K. D. Wells (Univ. of Connecticut), a male's mating success typically is affected by how long he remains at and calls from the breeding site. Depletion of muscle glycogen apparently limits a male's ability to call on a per-night basis. Depletion of stored lipids may constrain his ability to call over the course of the breeding season. Selection has apparently acted to maximize male calling ability via physiological mechanisms, for trunk muscles have the highest aerobic capacities in those frog species in which males call the most.

J. J. Schwartz (Univ. of Missouri, Columbia) developed this theme further, illustrating the problems faced by calling males in the treefrog *Hyla microcephala*. In order to maximize his chances of mating, a male in a dense chorus of competitors should call at a high rate. But there's a catch; he must ensure his calls stand out against those of other males, but calling is energetically costly. Males appear to solve this dilemma by altering the temporal structure of their calls. On a fine time-scale, males avoid acoustic overlap with calls from their loudest neighbors (as Schwartz determined using some very clever, home-grown equipment). On a coarser scale, chorusing males call in distinct bouts separated by periods of silence. This appears to be an energy-saving tactic for, without these quiet periods, males would be unable to call for long periods due to depletion of glycogen reserves.

The issue of constraints on sexual selection was also discussed by T. Halliday (Open Univ., England). He began by pointing out that patterns of mate choice and competition (in both females and males) should depend, at least in part, on which sex can mate at the fastest rate (see Clutton-Brock and Parker 1992). Halliday illustrated this point with examples drawn from work on European anurans and newts. In addition, he suggested that constraints on mating performance should be considered at two levels: within a single mating episode, and in terms of the interval between one episode and the next. Different kinds of constraints may operate at these two levels. For example, while oxygen availability may limit the courtship performance of a male newt courting under water, time constraints on his ability to synthesize components of spermatophores may limit the frequency with which he can engage in multiple matings over longer periods of time.

Not all males in a population engage in "conventional" sexual behavior, such as fighting with rivals and courtship of females. In many animals, including many fishes, some males in a population adopt alternative sexual behavior patterns, such as sneaking and satellitism. M. R. Gross (Univ. of Toronto) discussed the evolution

of such alternative behavior patterns, especially in species in which males seem unable to switch between alternatives. He stressed that two classes of alternatives exist. First there are "strategies," in which the fitness of alternatives is more-or-less equal due to frequency-dependence. Then there are "tactics," which arise when males differ in status, and among which fitnesses are not necessarily equal. Gross concluded that most alternatives should be regarded as "tactics," because most reveal unequal fitness when carefully examined. Males of inferior status may be forced into adopting alternative tactics in order to "make the best of a bad job" (Dunbar 1982).

The suitability of reptiles as subjects for studies of sexual selection was discussed by A. S. Rand. In an entertaining but informative talk, Rand proposed that such phenomena as territoriality, lack of extensive parental care, conspicuous behavior patterns, and ease of manipulation make certain reptiles, especially iguanid lizards, ideal subjects for the study of different kinds of sexual selection. For snakes, Rand suggested that the complex hemipenes of most species make them suited for work on "cryptic" female choice based on individual differences among males in genitalic structure (Eberhard 1985).

The reptilian theme was developed further by D. K. Hews (Arizona State Univ.) in her discussion of male-male competition in lizards. She noted that sexual dimorphism is common in these animals, for both behavioral and morphological characters. Furthermore, she described examples of alternative mating tactics among males in several species. Hews suggested that the evolution of lizard sexual behavior should be viewed in an explicitly phylogenetic context, and that certain species may be amenable to studies of the proximate causes of such characteristics as sexual dimorphism (say, through endocrine manipulation).

The issue of proximate causes was also considered by A. J. Tousignant and D. Crews (Univ. of Texas, Austin), for the gecko *Eublepharis macularius*. Like many reptiles (Janzen and Paukstis 1991), this species has temperature-dependent sex determination. Even more interesting, developmental events affected by incubation temperature can result in differences in physiology, growth, and behavior that persist into adulthood. These differences exist both between the sexes, and among individuals of the same sex! It isn't yet known whether such differences among same-sex geckos influence mating success. But if they do, then they may become targets of sexual selection.

Snakes have received far less attention than lizards in the study of reptilian sexual selection. A theoretical framework for snake work was developed by D. Duvall (Arizona State Univ., West), S. J. Arnold (Univ. of Chicago), and G. W. Schuett (Univ. of Wyoming). They outlined a new theoretical approach to sexual selection which combines selection theory with encounter rate theory in order to predict how male snakes should behave in order to maximize mating success, and then to predict actual mating systems. The approach worked well in explaining patterns of mating success in prairie rattlesnakes, and will undoubtedly prove useful for other animal groups.

Although female choice may be of somewhat limited significance in snakes (at least relative to other ectotherms), both intersexual selection and intrasexual competition are often involved in determining patterns of mating success among males. A. Kodric-Brown (Univ. of New Mexico) compared territorial and non-territorial males of the Pecos River pupfish. She found that territory holders are more colorful, more aggressive, and more successful in spawning than non-territorial males. Some male traits (such as color) seem selected because they are both preferred by females and advantageous in male-male competition. In addition, female choice based on traits that appear to reflect male health and vigor may perhaps yield a genetic benefit to the offspring of choosy females.

In other species, intersexual selection and intrasexual competition seem to work in opposite directions on the same trait. J. M. Ellingson (Univ. of Texas, Austin) reported that, in the gecko *Gonatodes albogularis*, head color (which is brighter in males than in females) is used to settle contests among males: yellow-headed males win. Although females prefer large, yellow-headed males over smaller, red-headed males, red-heads are preferred when males are matched for body size. For this reason, a male that succeeds in an agonistic encounter may not necessarily be chosen as a mating partner.

B. K. Sullivan (Arizona State Univ., West) discussed determinants of mating system structure in temperate bufonid toads, focusing on intraspecific variation rather than comparisons among species. He found that sexual selection is most intense when breeding seasons are long and operational sex ratios are male-biased (so that breeding males outnumber breeding females). Although competition among males is the most important determinant of who mates when breeding seasons are short, Sullivan showed that females may still exercise some choice of partners. He concluded that, as in many other animal species, the spatial and temporal predictability of females is most important in determining the exact structure of a toad population's mating system.

Mating systems in the dart-poison frogs (*Dendrobates*) involve some kind of parental care, and so are very different from those of bufonids. K. Summers (Queen's University, Canada) and E. Bermingham and L. Weigt (Smithsonian Tropical Research Institute, Panama) described both behavioral and molecular approaches to understanding parental care in these frogs. The genus includes species with biparental care, maternal care, and paternal care. The fact that females suffer decreased reproductive success if males mate polygynously is consistent with the hypothesis that female care evolved from male care. Molecular work now underway should provide a phylogeny for use in reconstructing the evolutionary history of patterns of parental care.

It is easy to forget that, for anurans, most of the early studies of vocalization were concerned with species recognition and sexual incompatibility among species, rather than sexual selection within species (e.g., Blair 1958). Many biologists today regard species recognition as something of an "epiphenomenon" arising from intraspecific sexual selection (e.g., Ryan and Rand 1993). This idea was developed by M. J. Littlejohn (University of Melbourne, Australia). He started by reviewing the significance of anuran calls within populations, stressing their role in attraction of females and repulsion of rivals. He then suggested that females may gain two types of information when they hear a call: the species identity of the calling male and his suitability as a mating partner (based, say, on his genetic quality and/or any resources he may be defending). The effect of perceiving male calls on female frogs was discussed further by W. Wilczynski (Univ. of Texas, Austin) from an explicitly neurological perspective. He reported that neuroanatomical studies of frog brains have revealed the presence of connections between auditory centers and areas controlling reproductive activity. It seems possible, if not likely, that these neural connections may enable acoustic signals to affect the reproductive physiology of listening females.

The extent to which sexual selection may drive divergence among conspecific populations was addressed by P. A. Verrell (Washington State Univ.). He reported that some conspecific populations are highly sexually incompatible with one another in the salamander *Desmognathus ochrophaeus*. Observations of between-population sexual encounters have revealed that, in some cases, male-female interactions cease at the point in the courtship sequence when males apply courtship pheromones to their partners. Within-population studies have shown that these pheromones increase the rate at which females become sexually responsive, and so appear to have evolved by sexual selection. In these salamanders, sexual selection may have driven the divergence of courtship pheromones, and so incidentally resulted in sexual incompatibility among some populations.

The fate of populations that are in contact with one another

(either primarily or secondarily) has long fascinated biologists. If matings between such populations result in wasted reproductive effort, selection may favor the evolution of differences in sexual behavior to ensure that mismatings do not occur. Previous studies have typically compared male courtship signals for populations allopatric to and sympatric with others, predicting that signals should differ more in sympatry than in allopatry if selection has acted to prevent mismating (Butlin 1987). However, H. C. Gerhardt (Univ. of Missouri, Columbia) reported that divergence of female preferences, rather than male signals, appears to be responsible for the absence of mating between sympatric populations in the gray treefrog complex. In fact, sympatric females were more responsive to a species-specific call parameter and less responsive to another that mediates intraspecific mate choice than were allopatric females.

The symposium officially ended with a general discussion among participants and members of the audience. Many areas were covered, but one theme that I think emerged especially strongly was that we need to consider sexual selection in the context of all aspects of life-history (see also Partridge and Endler 1987). Especially for males, mating tactics may be dependent on experiences early in ontogeny, long before the attainment of sexual maturity. For example, feeding history as a juvenile may influence a male's later sexual behavior (say, through an effect on body size and thus competitive ability). If sexual behavior then influences mating success, one could argue that early feeding behavior can properly be regarded as a target of sexual selection.

The symposium unofficially ended at an open-house hosted by Mike Ryan. Lubricated by ample supplies of beer and fueled by munchies, all of us agreed that we have a learned quite a lot from studying sexual selection in ectotherms. But we also all agreed that there is still an awful lot more to be learned in the future.

POINTS OF VIEW

Comments On The Taxonomic Arrangement Of Some Hispaniolan Amphibians And Reptiles

The evolutionary species concept (sensu Wiley 1978 and Frost and Hillis 1990) has recently been applied to amphibians and reptiles in both the eastern (Nilson and Andrén 1986) and western (Collins 1991) hemispheres. These applications have engendered numerous commentaries and replies (in temporal sequence: Schätti et al. 1991, Montanucci 1992, Van Devender et al. 1992, Lazell 1992, Collins 1992, Frost et al. 1992, Nilson and Andrén 1992, Schätti et al. 1992, Dowling 1993). Some addressed the relevance of the concept itself, others expressed greater concern over the methods by which it was applied. Proponents of the evolutionary species concept seek evidence to discern independent lineages. Some species may be polymorphic, but still historically cohesive. Other polymorphic assemblages are composed of evolving populations, operationally species.

Hispaniola and its satellite islands exist as a microcosm of various biomes, often only a few kilometers apart. The resultant biotic diversity, especially of amphibians and reptiles, lends itself well to examining the potential impact of applying the evolutionary species concept. Based on the best available published information (Schwartz and Henderson 1991), I have identified those taxa (Appendix 1) which exhibit two characteristics that indicate the possibility of species status: 1) they are distinctly mapped as allopatric, and 2) they have been formally diagnosed as being morphologically distinct. Suggestions regarding the validity of some of these species exist already; e.g., *Peltophryne fracta* (Powell 1992; Pregill 1981), *Aristelliger expectatus* (Cochran 1941), *Hemidactylus haitianus* (Powell and Parmerlee 1993), *Leiocephalus endomychus* (Pregill 1992), and *Amphisbaena hyporissor* (Powell 1992; Thomas 1965). In additional instances, data sufficient to draw definitive conclusions are lacking. These include: 1) wide-ranging colonizers (e.g., *Rana catesbeiana* and *Hemidactylus mabouia*) or established populations of more recently introduced species (*Anolis cristatellus* and *A. porcatus*); 2) at least some populations of species with broad insular ranges which include numerous distributional records of uncertain systematic status (e.g., *Ameiva taeniura, Anolis olssoni, Leiocephalus personatus, Epicrates fordii,* and *E. gracilis*); or 3) forms within the range of which intermediate localities in largely inaccessible areas are unknown (e.g., *Anolis barahonae, A. strahmi, Leiocephalus melanochlorus,*

Sphaerodactylus randi, and *Celestus haetianus*).

Excluding those situations listed above, 43 of the currently recognized Hispaniolan species may actually represent complexes containing as many as 92 specific taxa. Of the 43 possible complexes, five are anurans, one a turtle, 30 are lizards, one an amphisbaenian, and six are snakes. If one relates these to the species composition on Hispaniola, the resultant ratios quickly indicate that anuran species complexes are underrepresented when compared to those of reptiles. Alternative hypotheses include: 1) insular anurans speciate more rapidly than reptiles, resulting in more species of limited distribution—or conversely, fewer polymorphic species with broad distributions; 2) relatively more species of Hispaniolan reptiles have broader tolerances of varied habitat conditions, resulting in a greater number of wide-ranging polymorphic species; or 3) historically, systematists working primarily with anurans have used different criteria for species recognition.

The third alternative cannot be discarded out of hand, especially as the large number of subspecies among the Hispaniolan herpetofauna are largely the result of Al Schwartz's eye for detail. Schwartz recognized polymorphism in nearly every species with a range extending beyond the type-locality, particularly the diurnal lizards and snakes. Thus the high number of subspecies in the West Indies, compared with comparable diversities elsewhere in the Neotropics, is not surprising. Still, substantial support for the alternative hypotheses can be generated by examining those species complexes containing more than two diagnosable allopatric forms. Only two are frogs, while 15 are lizards and four are snakes. The majority of these taxa have broad, often island-wide distributions. Especially prone to the development of diagnosable populations are lizards of the genus *Ameiva*. *Ameiva lineolata* may represent a complex of as many as six, *A. chrysolaema* as many as eight, and *A. taeniura* as many as ten species. Although comprising a range of habitat preferences from decidedly xerophilic (*A. lineolata*) to mesophilic (*A. taeniura*), as a group these teiids historically occurred in all but the densely forested higher elevations on Hispaniola. These mountain ranges partition lizard populations in the intervening lowlands into discrete entities by limiting gene flow. Further instances of allopatry result from populations inhabiting satellite islands. Less diverse, but similar examples are represented by the *Anolis distichus* (up to five Hispaniolan species, as *A. dominicensis*) and *Celestus costatus* (up to six species) complexes among lacertilians, and by the *Antillophis parvifrons* and *Uromacer catesbyi* (up to five species each) complexes among snakes.

Proponents of the evolutionary species concept have argued that it not only reflects the appropriate phylogenetic (= historical) perspective of systematics, but that this historical view is the only philosophy capable of providing a realistic measure of natural species diversity. The latter is particularly important as biologists, especially in developing nations, are desperately attempting to develop conservation plans for biotas which have not been completely inventoried or for which inventories may include some species being misrepresented as subspecies. Even if only a subset of the Hispaniolan species elevated by application of the evolutionary species concept is valid, the inevitable (and I would argue justifiable) increase in species numbers can have a significant impact on evaluations of biodiversity and the resultant development of conservation plans. Regardless of one's preferred paradigm, this debate has focused considerable attention on what should be a fundamental and highly pragmatic concern, that of how many species exist in any given geographic area. As Dowling (1993) suggested, I would strongly recommend that herpetologists devote increased energy to examining and resolving the individual taxonomic questions that arise as a result of applying the evolutionary species concept on Hispaniola and elsewhere.

Acknowledgments.—Several colleagues read earlier drafts and commented on this manuscript with various degrees of agreement. I thank them for their input and respect their requests for anonymity. Gregory K. Pregill and an anonymous reviewer made a number of valuable suggestions. Joseph T. Collins encouraged this effort. Sixto J. Incháustegui, José A. Ottenwalder, Andreas Schubert, and Emílio A. Bautista M. often have facilitated opportunities for field work in the Dominican Republic.

Anonymous Reviews: Necessary Convention Or Outmoded Obscurantism?

One of the vital hallmarks of scientific publishing is the system of peer review. In this system, well known to anyone who has ever attempted (successfully or otherwise) to publish a scientific paper, the editor (of a journal, for example) sends out a submitted paper to an individual or individuals he or she thinks competent to prepare a critical review. It is largely on the basis of the response of these reviewers whether the paper will be deemed worthy of publication. This system is extremely important in assuring the quality of published scientific work.

It is not the purpose of this paper to debate the utility of the peer review system. We consider such to be above question. What we do wish to explore herein is the usefulness of the **anonymous** peer review system. In this variant of the system, the identity of the reviewers is withheld from the author of the submitted paper. Matters pertaining to the revision of said paper are funnelled through the editor of the journal. In this roundabout fashion, the business of the preparation of an accepted paper for publication is conducted. If an author has a question concerning the reviewer's comments, he writes to the editor; the editor writes to the reviewer; the reviewer writes back to the editor; and, finally, the editor writes back to the author.

Wilson has been the section editor for Serpentes for the *Catalogue of American Amphibians and Reptiles* since 1974. During that time, he has processed over a hundred mss. of *Catalogue* accounts. Unlike with most herpetological publications, he has never exercised his option to reject a submitted account. He has simply worked with the author of the account until it was deemed ready to be published. It is to be granted that these accounts are essentially reviews of the literature on a given taxon and, thus, are not going to be plagued with problems of faulty experimental design, statistical analyses, or conclusions, which are good reasons for rejecting papers sent to the professional journals. Nonetheless, by virtue of the fact that he works with an author until the account is in publishable form has meant, in some cases, a lot of correspondence back and forth between Wilson and the author, on the one hand, and the reviewer(s), on the other.

Over the 30 years that Wilson has been publishing, he has produced over 150 publications, ranging in size from one-pagers to books. McCranie has been publishing since 1976 and has produced slightly over 70 papers. We have dealt, therefore, with a large number of editors and reviewers. It is because of that experience that this paper has been written.

As is typical in our profession, every year one or both of us are asked to review several papers written by our colleagues. For the last several years, we have signed those reviews, indicating the desire that our identity be made known to the author(s) of the papers.

In attempting to assess views on this subject at potential variance with our own, we have spoken or corresponded with an eclectic, but idiosyncratic set of colleagues, among whom are the current or past editors of the four major herpetological journals in this country (Janalee P. Caldwell and Laurie J. Vitt, former general herpetology coeditors for *Copeia*, Samuel S. Sweet, former editor of the *Journal of Herpetology*, Robert G. Jaeger, editor of *Herpetologica*, and Martin J. Rosenberg, former editor of *Herpetological Review*). To each of these individuals and ourselves we asked two questions. The first one was, "Are you in favor of the anonymous peer review system used in our field?" The second one was, "Why or why not?" We also asked for their permission to quote their opinions in this paper. In this way, we have built a list of reasons both for and against the current system. These reasons are discussed below.

Reasons in Favor of the Anonymous Peer Review System

All of the editors of herpetological journals from whom we solicited comment on the anonymous aspect of the peer review system were fundamentally in favor of it. Most appeared to have given serious thought to the nature of the anonymous peer review system prior to our letter, and some indicated that they held no strong opinion on the subject, one way or the other. In all instances, however, the comments were well-conceived, thoughtful, and useful.

What follows is a summarization of the reasons the various editors that we contacted gave in favor of the anonymous peer review (their opinions subsume those of the non-editors we spoke with):

1. It is a means of protection of less well-established and less powerful people in the field from vindictive retribution by more prominent people capable of such acts, in the event that an unfavorable review is produced by the former. Such retribution might take the form of an unfavorable review on a paper in return, such as a review of a grant proposal, or a negatively critical response concerning the former's qualifications for an applied-for position.

Robert Jaeger provided the best example of what can result when "academic revenge" (Bob's term) is visited upon junior members of the academic community by senior members. He said, "I know of a person who was up for promotion for tenure and associate professor status. The department sought five outside letters of recommendation on the candidate. Four of the letters strongly favored promotion and tenure and one opposed both. The one opposing letter was from a senior ecologist whose paper, the year before, had been highly criticized in a review by the applicant for promotion. This one letter was used by the department head as a rationale for *not* recommending promotion for the applicant, because the applicant was perceived as not being broadly respected among his peers. I was on the faculty where this event transpired. The angry person whose paper had been reviewed by the applicant evaluated the applicant as immature and lacking high professional standards. The applicant, as you might guess, had signed his review and was, eventually, denied tenure largely on the basis of the one critical letter from a 'top man in his

field of research.' I was appalled at the time and am still amazed that such vengeance can exist in the academic community."

2. It allows free rein to the opinion of the reviewer to say what must be said concerning the merits of a reviewed paper. Martin Rosenberg opined that ". . . some reviewers might temper their words somewhat if they were asked to review a manuscript from a colleague who is also a friend or good acquaintance—and if they knew they would be identified to the author as the reviewer. This may not be a major concern when the review is positive, but it certainly is a possibility when the review is negative. To avoid such a situation, some reviewers might refuse to review some manuscripts or might reduce the intensity of their review, but not its general thrust."

3. It is the best way to obtain balanced reviews, given the concerns indicated above. Samuel Sweet provided a thoughtful discussion of this point of view. He said, "My own view is that anonymous reviews offer a closer approach to the overworked concept of a level playing field, simply because an author is obliged to consider the logic of the review without being influenced by the prominence or obscurity of the reviewer. If a reviewer's points are good, it really should not matter." Sam supported the merit of this opinion with a lengthy explanation, which we do not feel it necessary to quote here.

In summary, these editors fundamentally consider that the anonymous peer review system is a better way of guaranteeing the receipt of reviews that fairly assess the scientific merits of a piece of research, which are not influenced by the nature of the relationship between the author of the research and the preparer of the review (either one of friendship or enmity) or the relative stature of the two in the field.

Reasons Against the Anonymous Peer Review System

We have written this paper because we are not in favor of the anonymous aspect of the peer review system. We have spoken to other colleagues who also are not, but we consider it best not to ask them to subscribe to the reasoning provided below. What follows, then, is the set of reasons, presented in approximate ascending order of importance, why we think the anonymous feature of the peer review system should be abandoned.

1. The method is cumbersome and time-consuming. For an author to have a question concerning a review answered, he must become involved in a four-step process described in the second paragraph of the introduction. By way of contrast, if the reviewer's identity were known to the author, the latter could contact the former directly in a one-step process (with a copy to the editor to keep him informed). Given the use of the time-consuming approach now in vogue, the publication process is considerably lengthened and becomes more expensive.

2. The reverse side of the first reason discussed in the section above is that the anonymous peer review system provides the shelter of anonymity to those reviewers who would be vindictive. In essence, the editor and such a reviewer form a secret pact against the author. The author is known to both reviewer and editor. The author knows only the editor, who is not the author of the vindictive review. The vindictive reviewer has his vindictiveness thereby sanctioned; he is allowed to feed on his insecurities.

3. The anonymous peer review system is a type of academic dishonesty, which has no place in the scientific community. All scientists are held to exacting standards of ethical conduct. Violation of any of those standards is tantamount to expulsion from the field. As we all know, data have to be gathered scrupulously, hypotheses must be assessed fairly and without prejudice, and our published work must be squeaky clean. Science, unlike government, must always operate in the sunshine. We are all asked to take credit for our failures, as well as our triumphs. Why is it, then, that there is this part of science called the anonymous peer review system that is allowed to operate in the shadows? Why does the author have to own what he writes, but the anonymous reviewer does not?

4. The anonymous peer review system can allow exercise of selfish behavior. In some cases, individuals with a proprietary interest in given areas of research may attempt to keep others from engaging in similar research by handing down unfavorable reviews. Thus, another type of unethical behavior can be fostered under this system.

5. The anonymous peer review system is cowardly. Following the line of reasoning developed in the section immediately above, people who do not sign their reviews do not have the courage of their convictions. They are uncourageous, a synonym of cowardly. That the intellectual courage we demand of the author should stand alongside the cowardice allowed of the reviewer is paradoxical and unworthy of the dignity of our profession, indeed.

6. Because of the problems outlined above, the anonymous peer review system discourages cooperation among scientists. Cooperation is one of the hallmarks of the biologist's concept of society and traditionally science has hewed to the strictest form of cooperation existing in human society, transcending bounderies of politics, race, and religion. Surely, we do not wish to maintain the disoperative anonymous peer review system in view of its ability to strike at the very heart of the nature of scientific inquiry.

Conclusions

Little doubt should remain about our opinion of the anonymous peer review system. We think it is unprincipled, unethical, uncooperative, unscientific, and unwarranted. We appreciate the opinions of the editors we consulted, and we can understand the widespread appeal those opinions have; but, in our opinion, what those in favor of the anonymous peer review system are favoring is the maintenance of a system possessing the features indicated in the second sentence of this paragraph. Science in general, and the science of herpetology in particular, deserve a better quality of practitioner than the alternately vindictive and obsequious type of person described by our editorial consultants as the impetus for the existence of the anonymous aspect of the peer review system. With this paper, we are calling for a debate on this matter throughout the field of herpetology. For our part, we strongly suggest that this type of review system be abandoned in our field and be replaced with an acknowledged or nominal peer review system. Furthermore, we see no use for it in any other field of science. We also feel that it should be done away with by granting agencies, such as the National Science Foundation. As long as the kind of people who serve as the reason for the existence of the system are allowed to operate in its shadows, science will continue to be ill-served.

Acknowledgments—We are very appreciative of the time and effort the editors that we consulted undertook to respond to our request for their opinions on the merits of the anonymous peer review system, even though we do not necessarily agree with them. Our paper would have suffered without their help. We are also thankful to Roger Conant and Kenneth L. Williams for their opinions, so much so that we have not asked them to subscribe to the incendiary remarks we have made in the section arguing against the maintenance of this system. The collegial spirit is alive and well in these people.

TECHNIQUES

Use Of Fluorescent Pigment For Tortoise Nest Location

Works on assessment of reproductive potential in chelonians are frequently based on information obtained in a laboratory, from dissections and induced oviposition by oxytocin injection (Ewert and Legler 1978) or observations of captive animals. The location of nests in the field normally involves a much greater investment of time and effort, depending on behavioral and habitat specific aspects of each species. The most commonly reported methods are the monitoring of well known egg-laying sites and the focal monitoring of females about to oviposit, usually in combination with methods such as x-rays to assess pregnancy (Gibbons and Greene 1979), radio-tracking, or direct observation.

For European land tortoises, Stemmler-Gyger (1963, 1965) and Kirsche (1966) reported nesting activity of captive individuals through direct observation. Swingland and Stubbs (1985), in a field study on the reproduction of *Testudo hermanni*, located nests by searching for females in the egg laying process. Hailey and Loumbourdis (1988), working on energetic aspects of reproduction in *T. graeca*, *T. hermanni*, and *T. marginata*, combined x-ray, oxytocin injections, and monitoring of focal individuals to assess nests.

Fluorescent pigment marking has been used for general tracking of animals: small mammals (Duplantier et al. 1984; Lemen and Freeman 1985; McShea and Gilles 1992), fish (Phinney 1969), salamanders (Ireland 1973), lizards (Fellers and Drost 1989) and tortoises (Blankenship et al. 1990; Butler and Graham 1993). In this study I describe the use of fluorescent pigment to locate the nests of spur-thighed tortoises (*Testudo graeca*).

In a study of the activity patterns and reproductive biology of a *T. graeca* population from Doñana National Park (southwestern Spain), the method used was that of thread trailing, first developed by Breder (1927). Low density of individuals rendered active searching for nesting females unproductive. Nests are scattered randomly through the heath habitat and are too unconspicuous to be detected by visual searching. Not even the careful checking of the thread trail was enough to locate them. Oxytocin was not used because the natural nesting behavior of the females could not be accelerated or altered in any way.

Hence, to locate the nests of the thread-trailed females, they were x-rayed every 15 days during the egg laying season. Those which showed hard shelled eggs were released with the thread trackers and an additional patch of rabbit fur glued to the plastron. The fur was impregnated with fluorescent pigment powder (Swada Co., London). Every evening the route was first checked with the thread trail until the female was found at its resting site. The animal was then weighed and, if there was enough weight loss to indicate oviposition (Turner et al. 1984), the same route was followed during the night for the trail left by the pigment. A car lantern was used as a UV-light source, where the conventional fluorescent tube was replaced by a 6 VA UV-light tube, powered by a 12 V portable battery. Four colors of pigment (Fiesta Daylight Fluorescent Pigments, series E) were tested: aurora pink, rocket red, fire orange, and lunar yellow. In the UV-light, however, only the yellow, orange, and red hues were distinguishable. Pink and red were identical. Pigment impregnation was renewed each day, and each female received a different color from the day before. An average of 7 days (min. = 1 day, max. = 15 days) elapsed between the detection of the eggs through radiograph and oviposition. During this period females moved an average of 120 m/day (min. = 3 m, max. = 297 m).

The pigment draws a much more precise picture of the animal's trail than the thread, showing minor digressions like loops and back and forth movements. Furthermore, it indicates spots where the tortoise rested for some reason (e.g., basking, eating, nesting), through accumulation of pigment. The nest is not visibly distinguishable among these resting spots: these must be checked manually for soft substrate, and careful digging immediately reveals the eggs, which are always within 5–6 cm beneath the surface.

Pigment was washed away to a considerable extent by heavy rain, but the trail was still visible after 2–3 days and the nests could be found. No harmful effect due to the tracking devices was noticed, nor did these seem to alter the normal behavioral pattern of the tortoises. According to data from the manufacturer, toxicity of the pigment is very low. Further, the pigment trails showed that the tortoises rarely use the same path, and so run a very low risk of eating plants covered with the powder. Inspection of eggs revealed no trace of pigment on the shells.

During the nesting seasons of 1990 and 1991 (April to June) 24 pregnant tortoises were monitored, yielding a total of 31 nest sites, since 7 females had double clutches. In one case the thread-trailed female was found nesting, and a second nest was found by checking propitious points along the thread trail. In the other 29 cases the pigment method was employed. In two cases only the pigment was used. These two females were lost before nesting due to convergence of pigment trails from successive days before laying the eggs.

In 27 cases the females were followed with the combination of thread-trailing and pigment. Twenty-one nests were searched for on the same day of egg-laying or up to three days later; six nests were looked for 15–60 days later. Twenty-two of the 27 nests were located. Three of the failures occurred because the pigment had faded away, and the other two females were lost after running out of thread and pigment following exceptionally long movements before egg-laying (more than 400 m).

The simultaneous use of thread-trailing and pigment marking has the advantage of (1) permitting the detection of oviposition apart from the use of the pigment, sparing the effort of several nights of unnecessary UV-tracking, and (2) minimizing the chances of losing an animal due to mixing of pigment trails from successive nights—pigment persists on the ground for many days. This method is particularly suitable for low density populations, where searching for nesting females is unproductive and where there are no specific egg-laying sites. In this way, many nests may be located, with the additional advantage that each nest may be associated with a specific female.

Acknowledgments.—To Rafa Villafuerte, for the first insight on the use of this technique. This study is part of project CICYT-CSIC PB88-0009, and is also financed by a grant from ICI-AECI (Spain) and by Junta de Andalucía (Spain).

A New Method For Making Waistbands To Mark Anurans

Several published methods for marking anurans allow for the identification of individuals from a distance, thus eliminating the need to handle the specimens. For example, Nace (1982) sewed strings of colored beads into the forearms of African clawed frogs, *Xenopus laevis*, and Robertson (1984) glued squares of reflective sheeting to the heads of the leptodactylid *Uperoleia rugosa*. Both of these techniques required slight traumatization of the specimens in order to apply the label, although both markers reportedly remained on for extended periods of time (several weeks in Robertson 1984, several years in Nace 1982) and were eventually tolerated by the frogs. Elmberg (1989) devised a less injurious label which consisted of small plastic fish tags tied around the knee of a frog. However, Elmberg stated that these tags were useful for long-distance identification only if different combinations of color and right/leg application were used. A variety of waistbands, either color-coded (Emlen 1968; Wells 1977, 1978), or numbered (Howard 1978; Ryan 1980) have also been used to mark anurans, but some problems with these labels have also been reported. Wells (1977, 1978) had to replace tags every few weeks, and waistbands used by Ryan (1980) often fell off when his frogs moved onto land. Despite variable success, waistbands are effective labels because they can be applied quickly and non-invasively if the proper materials are used, and they can be constructed large enough to be observable from long distances. We describe below an inexpensive method for making waistbands which are large and visible but lightweight, and thus do not affect the mobility of anurans.

Our waistbands consist of surgical thread sewn through a square patch of surveyor's flagging. The thread is tied around the waist of the specimen so that the patch of flagging lies flat on the dorsal surface. A patch of ca. 1.5 cm x 1.5 cm and 0.03 g is used for individuals between 35 and 60 mm snout-vent length. Different colors of flagging can be used to identify different species, and a unique number can be written on the patch with a waterproof marking pen to identify individuals. The thread must be tied loosely enough to allow for some growth but tightly enough so that it does not slip off. Frogs appear to tolerate the waistbands since we have never observed any attempts by individuals to remove these tags. We recommend that the waistbands be checked weekly because they quickly become too snug and eventually cause chafing in newly metamorphosed, rapidly growing individuals. Approximately 95% of the waistbands remain on small frogs until removal is required after 2-3 weeks. We have made no observations of the effects of these waistbands on adult frogs that grow at a slower rate.

These waistbands are very lightweight and do not appear to impede the locomotor capabilities of anurans. We conducted a simple test to determine the potential effect of the waistbands on the jumping ability of the frogs. The test specimens were twelve recently metamorphosed green frogs, *Rana clamitans*, (30-37 mm SVL, 2.50-4.00 g mass). These frogs were randomly divided into two groups, and on every test day the frogs were induced to jump once by placing them on a 100 cm^2 Plexiglas shock pad which administered a single 13.4V shock and therefore stimulated the frogs in a standardized, consistent manner. This shock sequence had been used by us in other experiments, and we never observed loss of coordination or physical trauma in any specimen even after repeated shocks. The two groups were alternately tested either with or without a waistband over a six-day period so that each frog was tested three times with a waistband and three times without. All jumping distances were divided by the cube root of the mass of each frog in order to reduce the variation within the samples. The jumping distances/$mass^{0.333}$ of the 3 tagged and 3 untagged trials for each frog were averaged, providing a mean tagged and a mean untagged jumping distance/$mass^{0.333}$ for every frog. The differences between the mean tagged and mean untagged jumping distances/$mass^{0.333}$ for all frogs were compared with a two-tailed paired difference Student's t-test to determine if there was any contrast between the tagged and untagged trials.

No significant difference was detected in the jumping distance/$mass^{0.333}$ of the frogs whether or not they were tagged ($df=11$, $t=0.679$, $p=0.511$). The mean jump distance/$mass^{0.333}$ for all frogs was $11.47\ mm/g^{0.333} \pm 1.14$ SE when untagged as compared to $12.16\ mm/g^{0.333} \pm 1.15$ SE when they had tags on. These data suggest that the waistbands had no observable effect on the locomotor ability of the frogs.

These waistbands can be applied quickly by one person without invasive measures and they are large but lightweight. Therefore, this method should prove especially useful for behavioral studies in which individuals must be marked with minimal stress and observed without handling. This type of waistband might also be useful for marking urodeles and lizards. Several aspects of this technique remain to be evaluated, including their potential utilization in marking adult and larger frogs or specimens used in field studies.

Acknowledgments.—We thank S. Guttman for reviewing this manuscript, D. Groggel for help with the statistical design, and H. West for assistance with animal care.

A Simple Stomach Flushing Method For Ranid Frogs

Since reports of declines among amphibian populations have been postulated (Roberts 1992; Wake 1991), killing frogs for dietary analyses is even less justified. Stomach flushing has become an increasingly favored alternative to killing organisms to obtain diet data. Flushing techniques are especially useful for dietary analyses of protected species or populations under long-term study. To date, such techniques have been successfully used in a variety of groups including fishes (Dos Santos and Jobling 1988; Hopkins and Larson 1990; Swenson and Smith 1973), crocodilians (Fitzgerald 1989; Taylor and Webb 1978), lizards (James 1990; Legler and Sullivan 1979), turtles (Balazs 1980), and salamanders (Fraser 1976; Joly and Giacoma 1992). Although flushing techniques have been attempted on some species of frogs and toads (Gittins 1987; Joly 1987; Legler and Sullivan 1979), the method has not been extended to large ranid frogs.

This report describes an adaptation of the method of Legler and Sullivan (1979) and Joly (1987) to stomach flushing of ranid frogs with the use of anesthetic. We tested this method on frogs ranging in size from 45 to 150 mm snout-urostyle length (SUL), so it also represents the first application of stomach flushing to large ranids (> 120 mm SUL). The method presented here is well suited to field work; it requires a minimum of equipment, it is easy to use, and it is inexpensive to apply.

The flushing apparatus consists of a syringe to which flexible tubing is attached. The internal and external diameters of the tubing and the syringe size should be selected based on frog size. For frogs ranging in size from 45 to 90 mm SUL we recommend using a 2 mm internal and 3 mm external diam tubing and a 60 cc syringe, and for larger frogs, a 3 mm internal and 4 mm external diam tubing and a 100 cc syringe.

The frogs are immersed in an aqueous solution of the anesthetic tricaine methanesulfonate (MS-222) (1 g/l) until they lose righting response. Loss of righting response will require 5–15 min, depending on frog size and temperature of the anesthetic solution. The temperature of the anesthetic solution should reflect the temperature tolerance requirements of the species studied. When possible, frogs should be immersed in as warm a solution as possible to allow more rapid anesthesia. During our field work, we obtained best results when the anesthetic solution was at 28-30°C. We chose immersion rather than intracoelomic injection (see Letcher 1992) because of the convenience of its application in the field. The degree of anesthesia attained by the frogs was easily followed, and no previous body weight-specific dosage had to be calculated. However, caution is advised when first applying the technique to other ranids as some species may be extremely susceptible to anesthesia, necessitating in these cases weight-specific dosages.

Once sufficiently anesthetized, the frogs should be rinsed in fresh water to prevent overdose from residual anesthetic on the skin. While the frog is held belly up in one hand, its mouth should be opened with gentle backward thumb pressure on the skin of the throat or by gently inserting the flush tube into the mouth near the mandibular symphysis. Contrary to manipulations of unanesthetized lizards (Legler and Sullivan 1979) or crocodilians (Taylor and Webb 1978), no need existed to use a ring to keep the mouth open because once anesthetized, frogs offered no significant resistance. After the mouth is opened, the tube is inserted into the stomach with a little water for lubrication. The tube is moved around any food mass to the pyloric end of the stomach. Care must be taken not to enter the lung.

Once the tube is in place, the animal should be held head down in a vertical position and water pumped into the stomach. Initial pumping should be gentle and then increased enough to flush food. Abdominal contractions and expansion of the gular region signal imminent evacuation of the stomach contents. Usually a major bolus will emerge both preceeded and followed by fragments. Sometimes, it may be necessary to remove a large food item stuck in the throat with forceps. The food bolus and fragments are flushed directly into a sample bottle. Preservative is then poured in. Either 70% ethyl alcohol or 10% formalin is used as a preservative for food items depending on the type of analysis (counting or weighing prey) to be performed (see Howmiller 1972).

Frogs subjected to this flushing procedure were toe-clipped for future identification and to obtain a phalangeal sample for skeletochronological analyses (Leclair and Castanet 1987). After processing, frogs were held in a covered plastic bucket during recovery, which required less than 60 min. Frogs were released at their point of capture less than 24 h after being flushed.

Once one learns the technique, processing including anesthesia takes about 15 min. If frogs to be processed are staggered by placement in anesthetic at 5 min intervals, it is possible for two operators to process 9–10 frogs per hour.

We used the technique on three ranid species. Initially, it was tested on 3 *Rana pipiens* (52, 59 and 60 mm SUL). Those individuals were killed and only one still contained a 4 mm long homopteran. As we got accustomed to the technique we were later able to feel through the abdominal wall if food remained in the stomach.

We later applied the technique to *R. septentrionalis* (45–75 mm SUL) and *R. catesbeiana* (45–150 mm SUL). Three *R. septentrionalis* and one *R. catesbeiana* were killed and only small fragments representing less than 1% of the total food volume were not flushed from the stomachs. In the course of a study on sympatric populations of these two frog species during 1992, we stomach-flushed 236 individuals. We observed less than 1% mortality attributable to our manipulations: one male *R. septentrionalis* (50.5 mm SUL) died probably because of excessive exposure to anesthetic and a female *R. septentrionalis* (52.5 mm SUL) died because its lung was perforated by the flushing tube. Moreover, two *R. septentrionalis* and four *R. catesbeiana* captured during this study were flushed twice over roughly a one-month interval. In each case, the stomach contained food items; this led us to believe that these frogs were not significantly traumatized by the flushing process. One juvenile *R. catesbeiana* was flushed three times during a 41-day period without apparent ill effects. The only observable trauma the method caused was occasional irritation of the throat mucosa or stomach evidenced by minor bleeding in a few specimens.

We tried to flush unanesthetized specimens of both *R. septentrionalis* and *R. catesbeiana*, but it was almost impossible to immobilize the limbs of the frogs, and they frequently removed the tube with their forefeet (see also Legler and Sullivan 1979). Since mortality is low, if anesthetic is properly applied, its use will greatly decrease handling time when flushing ranid frogs. Loman (1979) has shown that for *R. arvalis* and *R. temporaria*, most food is visibly affected by digestion within 6 h. Therefore, if the frogs are not to be processed soon after capture, we suggest placing them on ice packs to slow down digestion and facilitate prey identification. Aside from its simplicity, this field-tested method has proven useful in obtaining diet data on a broad size range of ranid frogs. Because this method avoids killing study organisms, it is useful for demographic studies where dietary information needs to be obtained by sampling with replacement. As a consequence, this method could prove essential to demographic studies of protected species or small populations.

Acknowledgements.—We thank Patrick Carrier and Emmanuel Milot for their technical assistance. Raymond Leclair and two anonymous reviewers provided very helpful criticism on an earlier version of the manuscript.

A Modified Drift Fence For Capturing Treefrogs

Drift fences have become standard equipment for catching amphibians, and their use has become central to studies of the demography, population dynamics, and behavior of amphibians (e.g., Christein and Taylor 1978; Gibbons and Bennett 1974; Gibbons and Semlitsch 1982; Pechmann et al. 1991; Semlitsch and Pechmann 1985). Typically, these fences are made of hardware cloth (e.g., Howard 1978, 1980; Storm and Pimentel 1954) or metal flashing (e.g., Caldwell 1987). Although these designs are very effective for many species, they are less effective for treefrogs, which have adaptations for climbing vertical surfaces (e.g., toepads) and can therefore scale these fences (Dodd 1991; Gibbons and Bennett 1974; Gibbons and Semlitsch 1981). In this note, I describe a fence that I developed and used during a study of the barking treefrog (*Hyla gratiosa*) and that appeared to be highly effective in intercepting treefrogs.

The fence consists of a support structure made of PVC pipe and nylon strings and a flexible barrier made of clear, roll plastic (see Figs. 1, 2A-B). The PVC supports are 1.27 cm diam and consist of one 61 cm vertical post and two 30.5 cm "arms"; these sections are glued into a T-joint using PVC cement. In each arm, a hole is drilled at each end of the arm, approximately 2.5 cm from the end of the arm; the nylon string from which the plastic barrier is suspended passes through these holes.

For the two-way fence described here, two flexible plastic barriers are made, one for each side of the fence. Each barrier consists of 7.62 m x 1.07 m sections of 0.08 mm (3 mil) thick, clear, plastic. This thickness provides a good combination of strength and flexibility, and the use of clear plastic allows one to see frogs caught in the fence without bending over. I used 7.62 m sections because the plastic used to make the sections came in rolls of this length; one could use longer or shorter sections. About 8 cm of the bottom edge of each section is folded over and sewn with a sewing machine to the rest of the plastic to produce a tube 2.5 cm diam running along the bottom of the entire length of the section (Fig. 2A). The tube is filled with sand, and the weight of the filled tube holds the fence in contact with the ground; the flexibility of the tube allows it to conform to the shape of the ground. The sand-filled tube is placed on the ground next to the base of the T-supports, and the plastic barrier is attached to the two nylon strings with clothes pins placed about 1 m apart.

To install the fence, the PVC supports are placed 1.5–2 m apart and pushed into the ground approximately 10–15 cm (Fig 1A). Once the supports are in place, nylon strings are threaded through the holes in the arms. Depending on the size and shape of the pond, it may be easier to do this in sections (e.g., one-half or one-third of the pond at a time) because friction between the string and the supports eventually makes threading difficult. Once the strings are threaded and the sections of string are tied together, the strings are tightened so that they do not sag under the weight of the plastic barrier. The sections of the plastic barrier are placed at the base of

the supports with the sand-filled tube resting on the ground (Fig. 2B). Holes in the ground underneath the tube should be filled and obstructing vegetation should be cleared to insure that the tube rests snugly on the ground. The ends of adjacent sections are folded over each other and fastened with small (1.9 cm) binder clips. Binder clips are preferable to clothes pins because they are less likely than clothes pins to get caught on objects during the nightly installation of the fence.

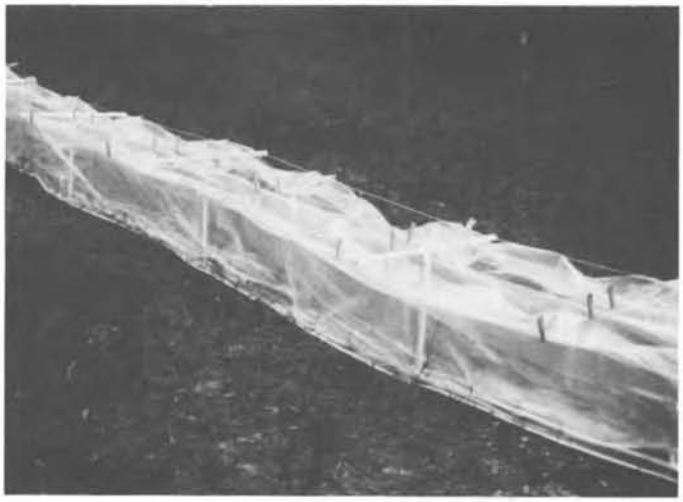

FIG. 1. Photograph of a fence for capturing treefrogs as they enter and leave ponds. See Fig. 2 for a diagram of this fence.

To allow animals to enter and leave the pond when investigators are absent and to prevent damage during strong winds or rain, the plastic barrier is rolled down and covered when the fence is not being monitored. Covers are made of 60 cm x 7.62 m sections of black roll plastic; each section is weighted down by sand-filled tubes (2.5 cm diam) sewn along the length of both sides of the section. Each time the fence is used, the cover is removed, and the fence plastic is suspended from the nylon strings, forming an inverted "L" (Fig. 2B). The plastic is attached to the string at 1-m intervals by folding a small piece of the plastic over the string and fastening it with a clothes pin (see Fig. 2C). Approximately 8–10 cm of the plastic is allowed to hang down from the outside edge of the horizontal part of the plastic barrier (Fig. 2A-C). One person can erect 42 m of two-sided fence in 30 min and lower and roll the same amount of fence in about 15 min.

As part of a study of the mating behavior of the male barking treefrogs, *Hyla gratiosa* (Murphy 1992), I estimated the effectiveness of the fence described here by calculating the percentage of male *H. gratiosa* that left the pond that had not been captured entering the pond. From 24 June to 4 August 1989, my assistants and I monitored a pond in the Ocala National Forest in Marion County, Florida. This pond was elliptical (20 x 50 m), and the edge of the pond was at least 30 m from the surrounding forest. Tall grass grew from the edge of the forest and into portions of the pond and was mowed in the areas where the fence was installed. We encircled the pond with 230 m of the two-way fence described here; the fence was located 10–20 m from the edge of the pond, which was far enough from the forest that frogs could not jump directly from the trees into the pond. Each night of the study, we erected the plastic barrier of the fence shortly before sunset and rolled it down at around 0200 h. Males and females begin arriving at the pond shortly after sunset, and by 0200 h all unmated males and females have left the pond, although mated pairs remain in the pond for at least another hour (Murphy 1992). We monitored the fence continuously by walking around the fence and capturing frogs that were intercepted by the fence; the amount of time required to check the full perimeter of the fence varied depending on the number of frogs intercepted by the fence (due to marking and handling time), but each point along the fence was checked at least every 15 min. This monitoring regime was chosen because the goals of the study of male mating behavior required us to maximize the number of individuals captured each night. On 23 of the 49 nights of the study, we attempted to capture males as they left the chorus. Of the 329 males caught as they left the pond during these 23 nights (some of which represent multiple captures of the same males on different nights), 309 (93.9%) had been caught as they entered the pond that night.

Several lines of evidence indicate that some of the 20 males that presumably escaped capture when entering the pond did not actually climb over the fence, but rather were already in the pond, having remained there overnight after being in amplexus the previous night. First, males were occasionally found during the day in the tall grass in the pond. Second, on a given night, the number of males caught departing the pond that had not been captured entering the pond was positively correlated with the number of females on the previous night that entered the pond and did not leave the pond before the fence was taken down (Spearman rank correlation, $r_s = 0.56$, $N = 21$, $P = 0.01$). These females presumably had mated on the previous night because females that mate do not leave the pond until after 0300 h, whereas females that do not mate leave the pond several hours earlier (Murphy 1992). Hence, the number of males that were captured leaving the pond but not captured entering the pond was correlated with the number of females presumed to have mated the night before, suggesting that they had been in amplexus the previous night. Third, of the 20 males that were captured leaving the pond but were not caught entering the pond that same night, eight (40%) were not caught leaving the pond the previous night after having been captured as they entered the pond that night, further indicating that these males were in amplexus. Three (38%) of these eight males were sighted in amplexus that night, and because no systematic searches for amplexed pairs were conducted, it is likely that the other five males were also in amplexus. If I exclude these eight males from the analysis, then the estimated effectiveness of the fence is 96.3% (= 309/[329-8]).

The behavior of frogs when they encountered the fence also suggests that the fence is highly effective. Upon reaching the fence, *H. gratiosa* usually climbed the wall of the plastic barrier. When they reached the corner between the horizontal and vertical portions of the plastic, frogs sometimes tried to move laterally, but they often remained motionless in this corner. During a four-year study in which the fence was monitored for over 3600 person-hours and in which over 12,500 captures of *H. gratiosa* were made, my assistants and I never saw a *H. gratiosa* climbing either along the underside of the horizontal portion of the fence or over the top.

Although several authors have indicated that traditional fence designs are less effective in intercepting treefrogs than in intercepting other species of amphibians (Gibbons and Bennett 1974; Gibbons and Semlitsch 1981), only one other study has estimated the effectiveness of a fence design in capturing treefrogs. In a six-year field study, Dodd (1991) employed a fence consisting of aluminum flashing and pitfall traps that he checked five days a week between 0700 and 0900 h; he estimated that the fence intercepted 93%, 86%, and 57% of the individuals of *Acris gryllus*, *Pseudacris ocularis*, and *Hyla femoralis*, respectively, that attempted to cross it. Of these three species, *H. femoralis* has the most developed adhesive toepads (Conant and Collins 1991) and is most similar to *H. gratiosa* in its climbing abilities (pers. obs.). However, a comparison of the relative effectiveness of the fence used by Dodd (1991) and the one described here is not valid because of the difference between the two studies in the frequency with which the fences were checked.

Although my research has focused on *H. gratiosa*, my assistants and I have routinely caught individuals of all of the species of anurans that visit or emerge from fenced ponds during my field

seasons (April–August); these species include *Acris gryllus, Bufo quercicus, B. terrestris, Gastrophryne carolinensis, Hyla femoralis, H. squirrella, R. catesbeiana, R. utricularia,* and juvenile *Rana capito aesopus*. I have not quantified the effectiveness of the fence in capturing these species, but my impression is that it is highly effective for all of these species except medium-sized and large *R. catesbeiana* and *R. utricularia*, which can leap over the fence.

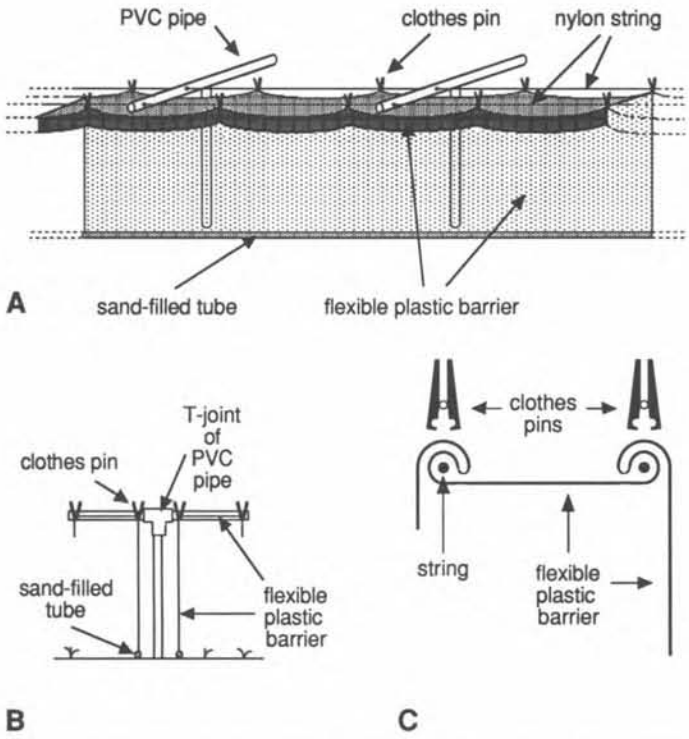

FIG. 2. Diagram of a fence for capturing treefrogs as they enter and leave ponds. A) Front view of the fence. Only a portion of the fence and only one of the plastic barriers are shown. B) Side view of the fence showing both plastic barriers. C) Enlarged side view of the fence showing method of attachment of flexible plastic barrier to strings.

There are some limitations to the design described here. First, I designed the fence primarily for species that tend to climb when they encounter obstacles; the fence may not be as effective in capturing species that are able to burrow under (e.g., *Scaphiopus*), or jump over (e.g., *R. catesbeiana, R. utricularia*) the fence or are large enough to dislodge the sand-filled tube from the ground by jumping against the plastic barrier (e.g., *R. catesbeiana*). Second, because my assistants and I checked the fence at least every 15 min, I do not know how effective the fence would be if it were monitored less frequently. Third, during heavy rains, the horizontal portion of the plastic barrier (the "roof") fills with water, and this added weight may cause the plastic to slip out of the clothes pins and fall. This problem might be alleviated by punching small holes in the roof of the fence with a paper hole-punch and reinforcing the plastic around these holes with duct tape. Fourth, the fence does not hold up well in strong winds if the plastic barrier is in place, although it can withstand heavy winds and rain when rolled down and covered. Finally, the plastic barrier becomes weak and brittle after continued exposure to sunlight; uncovered plastic that I left in direct sunlight usually lasted about two months. However, use of the black plastic covers described above extended the lifespan of the plastic barrier through an 81-day field season.

The fence that I have described is highly effective for capturing *H. gratiosa*, and is probably equally effective for other species of treefrogs. Use of this fence should facilitate efforts to gather information about the population dynamics, demography, and behavior of these species of anurans.

Acknowledgements.—I thank Mike Blouin and Sharon Forster-Blouin for helpful suggestions during the development of this fence and Jessica Boinoff and Steve Carpenter for assistance in collecting data on the effectiveness of the fence. I also thank Kraig Adler, Steve Emlen, Carl Hopkins, Harvey Pough, Paul Sherman, Mike Webster, and two anonymous reviewers for helpful comments on previous drafts of this manuscript. Funding was provided by the Nongame Section of the Florida Game and Fresh Water Fish Commission, and I thank the National Forest Service for permission to conduct research in the Ocala National Forest.

HERPETOLOGICAL HUSBANDRY

Observations On A Captive-Born Litter Of Typhlonectid Caecilians (Amphibia: Gymnophiona)

Various aspects of caecilian biology have been investigated in some depth, such as their unique jaw and trunk musculature (e.g, Bemis et al. 1983; Nussbaum 1983; Nussbaum and Naylor 1982) and urogenital systems and reproductive biology (e.g., Wake 1968, 1972, 1977), including investigations of the foetal teeth of typhlonectids, specialized for rasping the walls of the maternal oviduct for nourishment (Parker and Dunn 1964; Taylor 1968; Wake 1976, 1977). There is also significant literature regarding their taxonomy and descriptive morphology (Nussbaum and Wilkinson 1989; Savage and Wake 1972; Taylor 1968; Wilkinson 1989). Ecological and life history information regarding caecilians is however very limited, partly due to their reclusive habits and strictly tropical distribution (Moodie 1978; Wake and Case 1975), and descriptions of any kind of behavior are similarly rare (Bemis et al. 1983; Murphy et al. 1977). Due to this paucity of available literature regarding behavioral and life history information of these secretive animals, I will here describe observations of a litter of captive-born caecilians (*Typhlonectes*), including size of neonates and female, gill attachments, and early feeding behavior.

A female caecilian was purchased in April 1990 from a commercial pet dealer who had no information on the animal's origin. The animal was identified as *Typhlonectes compressicaudus* based on external morphology (Taylor 1968; Wilkinson 1989), though it has been suggested that *T. natans*, a similar species, is more common in the pet trade. Unfortunately the specimen was lost before an exact post-mortem identification could be made. The caecilian was housed in a 41 x 20 x 25 cm glass aquarium with a gravel substrate, several flat rocks, two plastic plants, and water maintained at a depth of 16 to 20 cm. The water temperature was kept at 23±1°C with an electric 50-watt thermostatic heater, and a corner Biosponge filter provided aeration. This is very similar to housing used by Murphy et al. (1977), in which copulation was observed.

When first introduced to the tank, the animal moved about rapidly in an undulatory swimming motion, pausing to breathe at the surface every few minutes. This activity decreased gradually over the course of two days, after which it was rarely ever seen unless disturbed, spending most of its time hidden beneath rocks and gravel and only extending the anterior portion of its body from cover in order to breathe (observed very rarely). It was noted that the caecilian molted its skin sometime in the first two days after purchase. This skin was found in one piece draped through the plastic plants, and upon removal from the water collapsed into a slimy wad that defied any attempts to spread for investigation.

The caecilian fed readily on whole or cut-up earthworms (primarily *Lumbricus terrestris*) offered on forceps, and ate every one to two weeks to satiety. Worms were usually pulled under the substrate with a quarter-turn lateral twisting motion of the animal's body. This behavior is similar to that described for terrestrial *Dermophis mexicanus*, in which animals retreated into burrows with corkscrew spinning motions that effectively sheared prey into small pieces (Bemis et al. 1983). It was never observed to feed on guppies (*Poecilia reticulata*) kept in the same aquarium, and refused freshly dead fish offered on forceps, despite reports of this species feeding on fish chunks in the wild (Moodie 1978). It did on occasion eat pelleted fish food resting on the substrate.

After about three months in captivity, the animal began to show a reduced appetite, finally refusing food altogether, while it appeared to be growing stouter in girth. On the evening of 3 November 1990, two neonates were found in the tank, with three more discovered late the next morning. Of this litter of five, two were observed to still have attached gill sheets. One of these gill sheets was limp and apparently torn, having been tangled in a plant, while the other was still turgid, though tranluscent with a few flecks of red toward the periphery. Both individuals had lost their gills by the following day (5 November). The neonates had proportionately large heads with relatively prominent subdermal eyes, and bore the white marks of gill sheet attachments across the backs of their heads (Fig. 1). These sites showed no surface damage, only a lack of dark pigment. All breathed with pronounced gular pumping when lifted from the water, and surfaced very frequently (ca. 30 s apart) thereafter while observed.

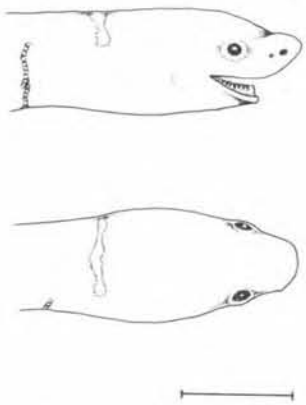

FIG. 1. Head of neonate *Typhlonectes compressicaudus* showing position of gill sheet attachments. Scale bar = 5 mm.

About 3 times over the next several hours, at least one individual was behaving sluggishly or lying limp on the bottom of the tank. Upon removal from the water, the neonate breathed vigorously and then struggled to reenter the water. To avoid further problems, I moved all offspring to a smaller tank (ca. 25 x 12 x 14 cm) with a low water level (ca. 2 cm). This container also had a gravel substrate with a few flat rocks, although no filter, and was kept at the same temperature as the maternal tank. Neonates could easily reach the surface to breathe while still anchored under rocks, whereas previously they had to swim or climb the plants to breathe, and the sluggishness observed earlier ended. Small pieces of earthworm (1–2 mm cubes) were refused, although two individuals prodded the bits with their snouts.

On 5 November, cast-off gill sheets and a white cylindrical object (presumably feces) were removed from the tank and preserved. Small pieces of earthworm were again offered, this time producing interest. Neonates were clumsy and the smaller individuals especially had difficulty maneuvering food into their mouths. One animal bit itself repeatedly, and all of them pushed at or bit at pieces of gravel in the vicinity of the worm bits.

One neonate (and the adult) were observed shedding their skins, though no skins were found in the tanks later, suggesting that these had been eaten. The adult female had also been observed eating a gill sheet shortly before young were removed from her tank.

All caecilians were weighed and measured on 6 November, when offspring were 2-3 days old, using an electronic balance and a metal meter stick. Individual measurements are reported in Table 1. The total mass of the litter was 12.64 g, which was 39.5% of the female's body weight. All animals were then photographed, returned to their respective tanks, and offered food. The female ate one small piece of worm, but neonates refused all offerings.

Moodie (1978) reports that pregnant female *Typhlonectes compressicaudus* in Brazil ranged in size from 450 to 800 mm in length, with litter sizes of 6 to 14, with a possible correlation between

female length and litter size. Wake (1977) reports a a comparatively small female *Typhlonectes* of 330 mm that gave birth to offspring of 200 mm, and notes that litters contained up to nine young. Parker and Dunn (1964) report a fetal *T. c. compressicaudus* to be 135 mm in length, and Heimroth (1915) describes normal neonates as 190–200 mm in length. Both my female and her litter were smaller than most of these values. In fact, my neonate sizes were well below that of 175 mm reported for prematurely born *T. compressicaudus* (Peters 1874), although free-living individuals with adult dentition are reported as small as 140 mm in length (Parker and Dunn 1964). It is unknown whether the small size of these neonates reflects a particularly small and/or young female or a population difference, since the precise origin of my animal is unknown.

TABLE 1. Weights (grams) and lengths (mm) of a captive *Typhlonectes compressicaudus*, and her five offspring at 2–3 days of age.

Subject	Weight	Length
Adult female	32.02	353
Neonate 1	2.94	136
Neonate 2	1.96	123
Neonate 3	1.72	118
Neonate 4	2.52	126
Neonate 5	3.50	141
Neonate mean:	2.53	128.8

Over the next few months the neonates required a great deal of attention. Their skill at feeding improved slowly, and they refused foods other than finely chopped worms (*L. terrestris*). Several varieties of dried and frozen prepared fish foods and live "blackworms" purchased at an aquarium specialist's store were offered at the suggestion of other caecilian owners, but were refused by my animals.

The two smallest neonates died within three weeks of birth, without ever effectively feeding. The third died after approximately one month while the last two survived to about three months of age. The last two neonates had been observed feeding regularly, but were apparently killed by infections of bites from *Poecilia*. It is interesting to note that Moodie (1978) reported that *Typhlonectes* skin secretions were toxic to fish, whereas I observed *Poecilia* biting neonates with no apparent ill effects to the fish.

Acknowlegments.—I would like to thank W. Parker, T. Henley, and an anonymous reviewer for helpful comments on the manuscript.

LIFE HISTORY NOTES

Instructions for contributors to Life History Notes appear in Volume 24, number 1.

CAUDATA

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). **DEVELOPMENTAL POLYMORPHISM**. Mature branchiate morphs (= paedomorphic adults) are common in several *Ambystoma tigrinum* subspecies (see review in Collins et al. 1980. Copeia 1980:938–941), but have been noted only twice in *A. t. tigrinum* (both in Michigan: at one site in the Upper Peninsula, and one site in the northern Lower Peninsula [Hensley 1966. Herpetologica 20:203–204]). On 8 June 1992, DKS and EEW observed several mature branchiate *A. tigrinum* in two of a set of newly constructed experimental ponds on the University of Michigan's Edwin S. George Reserve, Livingston Co., Michigan. We collected one larva (SVL=32 mm, UMMZ 200733) and two adult female vouchers (UMMZ 200731-32). Both females were sexually mature and had likely bred in 1992. One female (SVL=109 mm) was reproductive stage 3 (Collins et al. 1988. *In* R. C. Szaro, K. E. Severson, and D. R. Patton [eds.], Proc. Symp. Management of Amphibians, Reptiles and Small Mammals in North America, pp. 45–53. USDA Forest Serv. Gen. Tech. Rep. RM-166) with numerous copora luteal scars, the other (SVL=112 mm) was reproductive stage 5, also with numerous corpora luteal scars.

The E. S. George Reserve is located ca. 39 km NW Ann Arbor and ca. 7 km W Pinckney. The Reserve is ca. 5 km^2, and has been maintained as a protected research area since 1930. The numerous water bodies on the Reserve and their associated amphibian communities have been described by Collins and Wilbur (1979. Occas. Pap. Mus. Zool. Univ. Michigan 686:1–34). They list at least 12 ponds on the Reserve where breeding populations of *A. tigrinum* have been found; no mature branchiate *A. tigrinum* have ever been seen on the Reserve. The experimental ponds were constructed in a newly fenced addition, contiguous to the northeast corner of the Reserve. The ponds are circular and lined with 20 mil PVC liners covered with 30 cm of soil. The pond array consists of 12 ponds, 1 m deep and 15 m in diameter, and nine ponds, 2 m deep and 30 m in diameter. The small and large ponds were constructed and filled in Fall 1988, and Spring 1989, respectively. The ponds were allowed to colonize naturally with the exception of two ponds in which fish were stocked. Amphibians now breeding in the ponds include *Rana catesbeiana, R. clamitans, R. pipiens, Bufo americanus,* and *Hyla* cf. *chrysocelis,* in addition to *A. tigrinum.* We collected the mature branchiate A. *tigrinum* from a large, fishless pond, and observed additional mature branchiates in an adjacent large, fishless pond.

There is considerable debate about the relative contributions of genetics and environment to the expression or evolution of the mature branchiate morphology. Mature branchiates can only exist in permanent, usually fishless, habitats. *A. t. tigrinum* typically breed in temporary habitats; permanent, fishless ponds are scarce throughout most of the range of eastern tiger salamanders. Our observations suggest that environmental factors may play an important role in the expression of this trait. There is no doubt that typical, metamorphosed *A. tigrinum* colonized the ponds originally, and this is the first record of mature branchiates on the Reserve. Thus, conditions in the experimental ponds might have suppressed metamorphosis resulting in the branchiate adult morphology (e.g., Werner 1986. Am. Nat. 128:319–341; Wilbur and Collins 1973. Science 182:1305–1314). Nonetheless, genetic characteristics of these populations may differ from those of *A. t. tigrinum* elsewhere in the range, and expression of this morphology may be closely tied to genetics. All known mature branchiate *A. t. tigrinum* are from Michigan (including the Upper Peninsula). Allozyme data suggest there are substantial genetic differences between northern (including Michigan) and southern *A. t. tigrinum* (Jones, unpubl.; H. B. Shaffer, pers. comm.). Data in Routman (*In press.* J. Evol. Biol.) suggest that absence of mature branchiate *A. t. tigrinum* is due to genetic constraints, and Jones (1989. Ph.D. dissertation, Arizona State Univ.) provided correlative evidence linking developmental polymorphisms and genetics of *A. t. nebulosum.*

ANURA

BUFO MARINUS (Cane Toad). **PREDATION.** *Didelphis marsupialis* is a large opossum that can exceed 5 kg in weight, and body lengths of 1 m. These omnivores occur below 1500 m and frequent watercourses in search of food (Gardner 1983. *In* D. H. Janzen (ed.), Costa Rican Natural History, pp. 468–469. University of Chicago Press). *Bufo marinus* is the largest bufonid in tropical America (Zug 1985. Pacific Sci. 29:31–50), reaching a length of 200 mm, and a weight of 1.2 kg.

Small mammals prey upon *B. marinus* (Cintra 1988. Herpetol. Rev. 19(4):82; Zug 1985. *op. cit.*). While at La Selva Biological Station, Heredia Province, Costa Rica (ca. 10°20'N, 84°00'W), we observed a *D. marsupialis* prey upon a *B. marinus.*

On 2 October 1990 at 1800 h an adult *D. marsupialis* (SVL ≈ 520 mm) ran across the lawn with a large *B. marinus* (SVL ≈ 150 mm) in its jaws. The opossum stopped beneath a stand of *Heliconia* sp. and dropped the toad. The toad raised its venter completely off the ground and inflated, and tilted its head downward, presenting the dorsal aspect of the parotoid glands. This defensive posturing did not deter the opossum. The opossum chewed on and around the parotoid and orbital regions for ca. 2 min then began to foam profusely at the mouth. Foaming continued for 4 min, while the opossum raked its oral cavity with its forepaws.

After the toad was dead, the opossum thoroughly chewed the inguinal region and legs. After 10 min the opossum carried the remains of the toad to a burrow. Attempts to recover the remains of the toad were unsuccessful.

TESTUDINES

APALONE SPINIFERA EMORYI (Texas Spiny Softshell). **COLORATION.** A large xanthic female softshell (MSB 53538; straight-line carapace 312 mm) was collected in the Rio Grande near Radium Springs, Dona Ana County, New Mexico, on 4 June 1988. Bill MacDonald was fishing for catfish, using live crawfish as bait, when he hooked this turtle. In life, overall coloration was lemon yellow, soft parts were dull yellow. The blotched pattern usually seen on the carapace of adult female spiny softshells was absent. The eyes had white irises and dark brown pupils. Of 119 New Mexican *A. spinifera* examined none possessed this coloration. To my knowledge, this is the first report of xanthic coloration in *A. spinifera* (Dyrkacz 1981. SSAR Herp. Circ. No 11. 31 pp.; Hensley 1959. Publ. Mus., Michigan State Univ. Biol Ser. 1(4):133–159).

Submitted by **CHARLES W. PAINTER,** Endangered Species Program, New Mexico Department of Game & Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.

CHELYDRA SERPENTINA (Snapping Turtle). **PREDATION.** The common crow (*Corvus b. brachyrhynchos*) is an opportunistic and omnivorous feeder (Bent 1946. Bull. U.S. Nat. Mus. 191:1–495; Goodwin 1976. Crows of the World. Cornell Univ. Press, 354 pp.; Wilmore 1977. Crows, Jays and Ravens and their Relatives. Davis & Charles Publ. Co. 208 pp.). Its diverse diet includes insects (especially beetles and grasshoppers), small mammals, crustaceans, mollusks, amphibians, snakes, young waterfowl, poultry, eggs of various species, large quantities of grain, and road-kill carrion. Crows also are habitual scavengers on garbage and human food scrapes.

On 26 September 1992 at 1230 h a common crow caught a hatchling snapping turtle (*Chelydra serpentina*) on the campus of Northern Illinois University, DeKalb County, Illinois. The crow apparently attempted to crack open the hatchling turtle by dropping it onto the pavement. The turtle measured 21.2 mm in total length and was deposited in the Northern Illinois University collection (HDW-NIU 1474). Occasionally in early spring snapping turtles nest near the Biological Sciences building, in tilled earth adjacent to a small stream and lagoon.

The common crow may drop hard-shelled food such as crabs and nuts from great heights in order to break open the shells (Goodwin 1976, *op. cit.*; Wilmore 1977, *op cit.*). We may have observed a variation of this technique. Alternately, the crow may

have been startled and dropped its prey item.

Predation of snapping turtle nests can be high, averaging 70% (range 30-100%) in a two-year study in southeastern Michigan (Congdon et al. 1987. Herpetologica 43(1):39–54), and 90% in northern New York (Petokas and Alexander 1980. J. Herpetol. 14(3):239–244). Major predators were raccoons and skunks. This note documents predation on snapping turtles by the common crow.

I thank Downey Hunter for his notes on this observation, and Randy D. Jennings for useful comments on the manuscript.

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115, USA.

CLEMMYS INSCULPTA (Wood Turtle). **REPRODUCTION**. Kaufmann (1992 Herpetol. Monogr. 6:1–25) recently described copulatory ties in *Clemmys insculpta* as preceded by gentle side to side shaking of the mounted pair. He has shown that most episodes of clasping, biting, and thumping with or without shaking are not associated with insemination.

On 11 October 1992, at 1430 h, I discovered a mounted pair of adult wood turtles on dry land, several feet from a shallow stream in Westmoreland County, Pennsylvania. Air temperature was 15.5°C, water temperature was 8-9°C, and stream depth was approximately 15 cm. The male was alert, his plastron was in tight contact with the female's carapace, and there was no cloacal contact. I carefully placed the pair in the stream. Without losing his hold, the male promptly began biting at the female's head area and gently shaking from side to side.

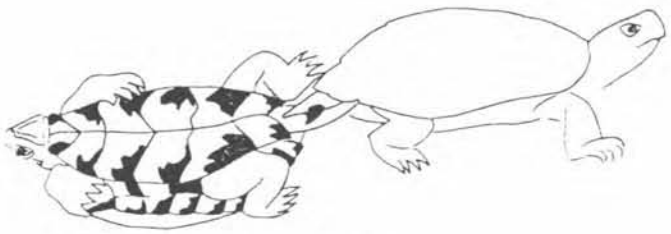

FIG. 1. *Clemmys insculpta* in copulatory tie.

I left the site and returned at 1505 h to find the pair in copulatory tie (Fig. 1). Approximately 3 mm of penile shaft was visible between the two tail vents. I watched for several minutes during which the male remained motionless, underwater. The female's head was above water; and she was breathing. When I gently tapped the male's plastron twice, he attempted to right himself. In doing so he pivoted around the point of cloacal contact until within reach of the female. He clasped her in plastron-to-plastron position, maintaining the copulatory tie (Fig. 2).

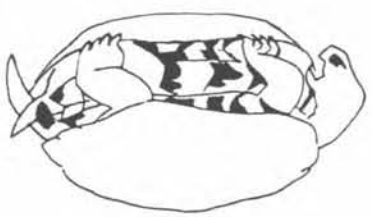

FIG. 2. Plastron-to-plastron copulatory position.

The male gripped the marginals of the female's carapace, not her plastron. Biting and thumping continued for approximately 20 min. By 1600 h the pair appeared fatigued. The male was clasping with front feet only; and the cloacae were no longer in contact. The turtles separated, remained beside each other on the stream bed for 5-10 min, and then moved apart.

While careful placement of the mounted pair into the stream and gentle tapping of the male carapace may have influenced the turtles' behavior, the observations reported here are in accord with Kaufmann's detailed report of copulatory ties preceded by shaking and expand the reported repertoire of mating behavior of *Clemmys insculpta* to include plastron-to-plastron clasping, biting, and thumping with maintenance of the copulatory tie.

GOPHERUS POLYPHEMUS (Gopher Tortoise). **BURROWS**. Gopher tortoise burrows are an important habitat for a wide range of species in addition to gopher tortoises (Jackson and Milstrey 1982. *In* J. E. Diemer, D. R. Jackson, J. L. Landers, J. N. Layne, and D. A. Wood (eds.), Proc. Gopher Tortoise Relocation Symp. Nongame Wildl. Program Tech. Rep., Florida Game and Fresh Water Fish Comm., Tallahassee). From October 1990 to February 1991, 73 gopher tortoise burrows were located on a 20 ha pine flatwoods/range site at the University of Florida, Southwest Florida Research and Education Center in Immokalee (Collier County), Florida. Burrows were classified as active (57) or inactive (16) following Auffenburg and Franz (1982. *In* R. B. Bury (ed.), North American Tortoises: Conservation and Ecology, pp. 95–126, U.S. Fish and Wildlife Service. Wildlife Res. Rep. 12.). In March 1991, 59 of the burrows were carefully excavated using a backhoe. No gopher tortoises were captured even though 78% of the burrows had been classified as active. However, eight other vertebrate species were captured or observed in 21 of the burrows including 4 green anoles (*Anolis carolinensis*), 5 squirrel treefrogs (*Hyla squirella*), 6 greenhouse frogs (*Eleutherodactylus planirostris*), 2 pinewoods treefrogs (*Hyla femoralis*), 1 ringneck snake (*Diadophis punctatus*), 2 eastern diamondback rattlesnakes (*Crotalus adamanteus*), 8 eastern box turtles (*Terrapene carolina*), and 3 cotton rats (*Sigmodon hispidus*). Ten burrows had bedding material suggesting that they were being used by small mammals. Seven of the 8 burrows with box turtles had originally been classified as active, while 7 of 9 that had frogs had been classified as inactive.

Submitted by **LAURA A. BRANDT**, **KENT L. MONTGOMERY**, **ARTHUR W. SAUNDERS**, and **FRANK J. MAZZOTTI**, Department of Wildlife and Range Sciences, University of Florida, P.O. Box 110430, Gainesville, Florida 32611-0430, USA.

LEPIDOCHELYS KEMPII (Kemp's Ridley). **NESTING**. Most of the world's population of *Lepidochelys kempii* nests along a small stretch of beach known as Rancho Nuevo in the Mexican state of Tamaulipas. Occasional nestings have been reported from elsewhere along the Gulf Coast of México, and a single nesting has been reported from the Gulf Coast of Florida (Ross et al. 1989. The Status of Kemp's Ridley. Center for Marine Conservation).

On 17 June 1992 a female *L. kempii* was observed and photographed nesting at Long Beach, Brunswick County, North Carolina. The turtle came ashore at ca. 1300 h EDT amid a large crowd of human beach visitors and laid 97 eggs in a nest dug just beyond the dune line before returning to the sea at ca. 1345 h EDT. The turtle had an estimated CL of ca. 60 cm. Several fish hooks with line were attached to the side of the turtle's shell; these were removed by onlookers. The turtle was not tagged, but bore a scar on the right foreleg where a tag may once have been attached.

Shortly after the nesting, the eggs were counted and moved to a safer location ca. 0.5 km W of the nest site by North Carolina Wildlife Resources Commission personnel. Forty-eight hatchlings emerged during the late evening of 26 August 1992. One dead hatchling was deposited in the North Carolina State Museum of Natural Sciences (NCSM 32024). Photographs of the nesting female are also on file at the NCSM.

Sally Murphy (pers. comm.) reported a *L. kempii* nest at Litchfield Beach, Georgetown County, South Carolina (ca. 50 nautical miles south of Long Beach) on 28 May 1992. That nest was carefully monitored, and 61 hatchlings emerged with assistance on 5 August from the 95 eggs that were laid. It is possible that these nestings were by the same turtle, although that has not been verified. These nestings are the first ever reported for *L. kempii* along the Atlantic Coast.

FIG. 1. Kemp's ridley (*Lepidochelys kempii*) nesting at Long Beach, Brunswick County, North Carolina, 17 June 1992.

I thank J. C. Beane, A. L. Braswell, and W. M. Palmer for assistance in preparing this manuscript, and Therese Conant, Sally Murphy, and South Carolina United Turtle Enthusiasts (S.C.U.T.E.) volunteers for sharing information on the hatchling data and the Litchfield Beach nesting.

LACERTILIA

AMEIVA EXSUL (Ground Lizard). **BEHAVIOR**. A large male *Ameiva exsul* was observed following a smaller female, the distance between them being approximately 2 m. When she was in his apparent line of vision, he walked directly toward her. When she was concealed, having moved behind a boulder or tuft of grass, the male followed her path through olfaction, indicated by rapid tongue flicking of the substrate. I have not found an account of the alternative use of vision and olfaction in a male *A. exsul*, trailing a female, in the literature available to me.

Submitted by **ARNOLD GROBMAN**, The Valley, Virgin Gorda, British Virgin Islands.

CNEMIDOPHORUS UNIPARENS (Desert Grassland Whiptail). **BEHAVIOR**. While presenting indirect evidence for the natural occurrence of pseudocopulation in the unisexual lizard *Cnemidophorus uniparens*, Crews and Young (1991. Anim. Behav. 42:512–514) noted that there were limited direct observations substantiating the occurrence and prevalence of this behavior in natural populations.

I spent June and July of 1991 and 1992 studying the foraging behavior of a natural population of *C. uniparens* located three miles east of Portal, Cochise County, Arizona. During these periods, pseudocopulation was observed four times (three times by me and once by a field assistant, Dennis Skalla). During 1991, this behavior was observed twice on 3 July and once on 4 July. In each of the 1991 occurrences, a foraging female approached another female who had crossed her path and mounted her in the manner depicted by the upper *C. uniparens* picture in Fig. 1 of Crews (1989. *In* R. M. Dawley and J. P. Bogart, (eds.), Evolution and Ecology of Unisexual Vertebrates. New York State Museum, Albany). Some of the females had been individually marked; there were four to six lizards involved in the three interactions, with a different combination of lizards each time.

Pseudocopulation was observed for a fourth time on 7 July 1992. As described above, a foraging female approached another female and mounted her while biting her neck. After 94 s, the biting lizard moved into the doughnut position shown by the lower *C. uniparens* picture in Fig. 1 of Crews (1989, *op. cit.*). The pair separated after a total contact time of 146 s.

These observations support the notion that pseudocopulation is a regular event in nature and provide some information on its seasonal occurrence.

HYDROSAURUS WEBERI (Weber's Sail-Fin Dragon). **MORPHOLOGY**. The holotype of *Hydrosaurus weberi* (MCZ 7505) collected at Weeda, Halmahera Island, Indonesia, has a bifid tail. Both branches of the tail are regenerated. The longer branch measures 98.8 mm (SVL=330 mm, tail=668 mm). The shorter branch measures approximately 11 mm and is encircled by at least four scale rows. Bifurcation occurs 533 mm from the cloaca. Tail autotomy and regeneration are poorly noted in the Agamidae. In fact, Moody (1980. Doctoral dissertation, Univ. of Michigan, 327 pp.) states that tail autotomy reportedly does not occur within Agamidae. At best, tail autotomy and regeneration occur sporadically within the Agamidae with the distribution of the trait within the family being unknown (Halliday and Adler (eds.) 1986. The Encyclopedia of Reptiles and Amphibians. Equinox Ltd., Oxford, p. 143; S. Moody, pers. comm.). This is the first report of tail regeneration and bifurcation in *Hydrosaurus*, and is likely the first known case of tail bifurcation for the Agamidae.

SERPENTES

ALSOPHIS PORTORICENSIS (Puerto Rican Racer). **DIET**. *A. portoricensis* is a West Indian colubrid snake known to feed in the wild on frogs (e.g., *Eleutherodactylus*), lizards (*Hemidactylus, Sphaerodactylus, Anolis, Ameiva*, and juvenile *Iguana*) and snakes (*Arrhyton* and *Typhlops*) (Henderson and Crother 1989. Biogeographic patterns of predation in West Indian colubrid snakes. *In* C. A. Woods (ed.), Biogeography of the West Indies: Past, Present, and Future, pp. 479–517. Sandhill Crane Press, Gainesville, Florida; Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville, Florida. 720 pp). However, information about specific prey items is lacking, and all but *Iguana* and *Arrhyton* are represented by several species on the islands where

A. portoricensis occurs. In Table 1 we list prey species taken by *A. portoricensis* at ten sites in Puerto Rico and other islands within the species range: Cambalache and Río Abajo Forest Reserves, Arecibo, Puerto Rico (PR) (Subtropical Moist Forests); Luquillo Experimental Forest, Luquillo, PR (Subtropical Wet Forest); and Guayama, PR; Water Island; Saint Thomas; Virgin Gorda; Caja de Muertos; Culebra; and Mona islands (Subtropical Dry Forests) based on stomach contents of an indeterminate number of preserved and live specimens.

TABLE 1. Natural prey species of *Alsophis portoricensis* taken at (1) Cambalache Forest Reserve, Arecibo, Puerto Rico (PR), (2) Luquillo Experimental Forest, Luquillo, PR, (3) Ranchos de Guayama, Guayama, PR, (4) Río Abajo Forest Reserve, Arecibo, PR, (5) Caja de Muertos Island, (6) Culebra Island, (7) Mona Island, (8) Saint Thomas, (9) Virgin Gorda, and (10) Water Island.

Our records confirm that *A. portoricensis* is an opportunistic predator on small vertebrates. Despite this, *A. portoricensis* employs different techniques when feeding upon *Anolis cristatellus* and *Eleutherodactylus coqui* (Rodríguez-Robles and Leal 1993. J. Herpetol. 27:163–168). Whether *Alsophis* also shows different behavioral repertoires when preying upon snakes and mammals deserves further study.

One *A. portoricensis* at Cambalache swallowed an *Eleutherodactylus antillensis* tail-first, whereas another at Guayama swallowed two *E. antillensis*, one head-first and one tail-first. In contrast, all the lizards that we recovered from snakes in the field were swallowed head-first. These findings seem to support our suggestions, based on observations of *Alsophis* during staged predatory episodes with *Eleutherodactylus* and *Anolis*, that *A. portoricensis* may use ventral scale overlap as a signal for head-first ingestion of reptiles (Rodríguez-Robles and Leal 1993, *op. cit.*). Although the ventral scales of *Diploglossus*, *Sphaerodactylus*, and *Anolis* exhibit some degree of overlap, those of *Ameiva* do not overlap at all. Hence, we hypothesize that *A. portoricensis* should not exhibit any preference for the direction of ingestion of *Ameiva*, which can easily be tested.

We thank M. Canals, J. C. Gillingham, and R. W. Henderson for sharing their records of natural prey items of *Alsophis portoricensis*, and H. W. Greene for reviewing the manuscript.

BOTHROPS ATROX (Common Lancehead). **DIET**. The most frequent prey of *B. atrox* are mammals, frogs, birds, and lizards (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Comstock Publ. Assoc., Ithaca, New York. 425 pp.) Puorto et al. (Resumos, XIV Congresso Brasileiro de Zoologia, Universidade Federal de Juiz de Fora, Juiz de Fora, p. 136) found a large (80 cm) colubrid (*Leptodeira annulata*) in the stomach of an adult *B. atrox* (total length = 72 cm). Ophiophagy has been reported for other species of *Bothrops* although no attempt has been made to quantify the importance of snakes in the diet of a single population (see references in Campbell and Lamar, *op. cit.*).

As part of a study on the feeding habits of *B. atrox*, the gut contents of 107 preserved specimens from Santa Rosa, the Estrada da Vigia, ca. 60 km northeast of Belém, Pará, Brasil (collected from 1973 to 1975), were examined. Santa Rosa is located in a deforested region with patches of remaining forests (see Cunha and Nascimento 1978. Publ. Avul. Mus. Para. Emilio Goeldi 31:1–218). All snakes were killed at the site of capture by locals during an intensive snake survey in the region (see Cunha and Nascimento, *op. cit.*). Each intact prey item or prey remain was recorded. Hair, feathers, and squamate scales were evident when present in the hindgut. When only insect remains were found in the hindgut we recorded the prey as a frog, because no insects were found in the foregut. After being dried with blotting paper, each snake and intact prey item (or a reference specimen of comparable size; Greene 1989. Proc. California Acad. Sci. 46:193–207) was measured to the nearest 1 mm with a flexible rule and weighed to the nearest 0.1 g with spring scales. Snake measurements are presented as snout-vent length (SVL) plus tail length. Prey/predator mass ratio (MR) was calculated when possible.

Fifty-four *B. atrox* from Santa Rosa had prey items in the gut. Two thirds of the snakes were juveniles with SVL's below 450 mm. The diet of the snakes was comprised of frogs (44% of all prey items), mammals (29%), lizards (11%), snakes (7%), centipedes (5%), and birds (4%). Four individual snakes were found as prey. Two nearly intact *Tantilla melanocephala* (183+53 mm 3.0 g; ca. 130+60 mm, 2.3 g) were eaten by a *B. atrox* measuring 437+80 mm (29 g; MR = 0.10) and 332+50 mm (14 g; MR = 0.16), respectively. Two additional individuals of *B. atrox* (333+57 mm and 378+59 mm) had the tail of a *T. melanocephala* and that of an unidentified colubrid. Except for one *T. melanocephala*, all snakes were ingested head first.

Most young *B. atrox* have yellowish cream tail tips that could be used as lures to attract insectivorous prey (see Greene 1992. *In* J. A. Campbell and E. D. Brodie (eds.), Biology of the Pitvipers, pp. 107–117, Selva, Tyler, Texas; Heatwole and Davison 1976. Herpetologica 32:332–336; Sazima 1991. Copeia 1991:245–248). *Tantilla melanocephala*, as well as centipedes, feed on invertebrates, including insects (Beebe 1946. Zoologica 31:11–52; Cunha and Nascimento, *op. cit.*) and may be attracted by caudal lures.

All snakes and some of their gut contents (including the snakes above) are deposited at the Museu Paraense Emilio Goeldi (MPEG), Belém, the State of Pará, northern Brasil. Logistical support and permission to examine snakes at MPEG were kindly provided by T. C. S. Ávila-Pires and F. P. Nascimento; S. G. Egler helped in laboratory work; I. Sazima and M. E. Oliveira provided helpful suggestions on the manuscript. The CNPq provided a grant to M. Martins. This note is a contribution of the Convênio Universidade do Amazonas/Instituto de Medicina Tropical de Manaus.

County record. Verified by P. V. Cupp, Jr. Eastern Kentucky University Department of Biology Collection (EKU 1100). New county record.

Submitted by **GLENN A. MARVIN**, Department of Zoology, University of Oklahoma, Norman, Oklahoma 73019, USA.

NECTURUS MACULOSUS (Mudpuppy). USA: TENNESSEE: Bledsoe Co: Sequatchie River at McWilliams Road crossing. 28 July 1992. T. Casey and B. T. Miller (Tennessee Scientific Study Permit 654). Verified by J. L. Miller. Middle Tennessee State University (MTSU 111-C). County record (Redmond 1985, A Biogeographic Study of Amphibians in Tennessee. Doctoral thesis, Univ. Tennessee, Knoxville. 290 pp.).

Submitted by **BRIAN T. MILLER** and **TIM CASEY**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

PLETHODON OUACHITAE (Rich Mountain Salamander). USA: OKLAHOMA: LeFlore Co: North Slope Spring Mountain, SE side of Forest Road 6007, 3.5 road km E jct. State Hwy 1, 488 m elevation. 5 November 1988. C. D. Anthony, M. E. Dorcas, J. R. Mendelson III, and J. A. Wicknock. Verified by J. A. Campbell. University of Texas at Arlington Collection of Vertebrates (UTA A-31154–31163). Spring Mountain is located 3.2 km north of, and parallel to, Rich Mountain, and directly east of Winding Stair Mountain. Although *P. ouachitae* occurs on both Rich and Winding Stair Mountains, the species has not been previously found on Spring Mountain. In subsequent years (1991–1993), we observed ninety-seven additional individuals on Spring Mountain in a continuous area 0.6 km W and 0.5 km E of the above locality. We found both the Rich Mountain and Winding Stair Mountain color variants of *P. ouachitae* (*sensu* Blair and Lindsay 1965, Copeia 1965:331–335) at these localities.

Submitted by **CARL D. ANTHONY** and **JILL A. WICKNICK**, Department of Biology, University of Southwestern Louisiana, Lafayette, Louisiana 70504-2451, USA.

PSEUDOTRITON RUBER (Red Salamander). USA: TENNESSEE: Cannon Co: wooded hillside off Sinks-Miller Road, ca. 8.7 km SE Rt. 64. 6 July 1992. B. T. Miller (Tennessee Scientific Study Permit 522). Verified by D. E. Metter. Middle Tennessee State University (MTSU 50-C, 51-C). Extends the known distribution into the low rolling hills of the eastern edge of the Outer Nashville Basin in middle Tennessee (Redmond 1985, A Biogeographic Study of Amphibians in Tennessee. Doctoral thesis, Univ. Tennessee, Knoxville. 290 pp.).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

SIREN INTERMEDIA NETTINGI (Western Lesser Siren). USA: LOUISIANA: West Carroll Parish: 0.1 road km S Newhope, Rt. 577, Sec. 35, T20N, R9E. 8 May 1992. L. Kemp and S. G. George. Verified by Neil H. Douglas. Northeast Louisiana University Museum of Zoology (NLU 70398). New parish record.

Submitted by **STEVEN G. GEORGE**, Department of Biology, Northeast Louisiana University, Monroe, Louisiana 71209, USA.

ANURA

BUFO COGNATUS (Great Plains Toad). USA: NEBRASKA: Deuel Co: 11.3 km N Big Springs. 28 June 1993. Carl E. Bock and H. M. Smith. Verified by David Chiszar. UCM 56783–4. County record (Lynch 1985. Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **HOBART M. SMITH**, **CARL E. BOCK**, and **JANE H. BOCK**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

BUFO COGNATUS (Great Plains Toad). USA: COLORADO: Logan Co: Rt 138, 3.1 km E Crook. 29 May 1982. W. Lippincott. National Ecology Research Center, Ft. Collins, Colorado (BS/FC 2339). Verified by Stephen Corn. New county record (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife, Denver. 131 pp.).

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA, **GEOFFREY A. HAMMERSON**, Nature Conservancy, 201 Devonshire Street, Boston, Massachusetts 02110, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA, and **CINDY RAMOTNIK**, U.S. Fish and Wildlife Service, National Ecology Research Center, 4512 McMurry Avenue, Ft. Collins, Colorado 80525-3400, USA.

BUFO MICROSCAPHUS MICROSCAPHUS (Arizona Toad). USA: ARIZONA: Gila Co: Pinto Creek at U.S. Forest Service Road 287, Sec. 2, T1N, R13E. 19 April 1993. S. G. Seim. Verified by B. K. Sullivan. To be deposited in Arizona State University Lower Vertebrate Collection (Field Series BK S371). One calling male observed 60 km SW nearest record (Sullivan, Great Basin Nat., *in press*). Not previously known to occur on south side of Lake Roosevelt.

Submitted by **SHARON G. SEIM**, Arizona Game and Fish Department, Nongame Branch, 2221 West Greenway Road, Phoenix, Arizona 85023, USA.

BUFO SPECIOSUS (Texas Toad). USA: TEXAS: Llano Co: 24.1 km SE Llano off County Road 310 at Sandy Creek, vicinity of Click. 30 May 1993. L. D. Gage. Verified by V. R. McDaniel. Arkansas State University Museum of Zoology (ASUMZ 19083–19085). New county record filling a distributional gap between Burnet and Mason counties (Dixon 1987, Amphibians and Reptiles of Texas, Texas A & M University Press, College Station, Texas, 434 pp.).

Submitted by **CHRIS T. McALLISTER**, Renal-Metabolic Lab (151-G), Department of Veterans Affairs Medical Center, 4500 South Lancaster Road, Dallas, Texas 75216, USA, and **STANLEY E. TRAUTH**, Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467, USA.

BUFO WOODHOUSII WOODHOUSII (Woodhouse's Toad). USA: SOUTH DAKOTA: Ziebach Co: Bald Eagle Ranch, 16 km E Howes. 31 May 1992. J. Bald Eagle & D. Chiszar. Verified by Todd Gleeson. UCM 56569; Haakon Co: S bank Cheyenne River at Rt. 34 crossing. 31 May 1992. A. Chiszar, L. Chiszar & D. Chiszar. Verified by J. Mitton. UCM 56570. County records (Fishbeck and Underhill 1959. Proc. South Dakota Acad. Sci. 38:107–113).

Submitted by **DAVID CHISZAR**, Department of Psychology, and **HOBART M. SMITH** Department of EPO Biology, both Museum of Natural History, University of Colorado, Boulder, Colorado 80309-0345 and 0344, USA.

HYLA GRATIOSA (Barking Treefrog). USA: TENNESSEE: Warren Co: on gravel road at Rt. 127 crossing of Collins River. 17 July 1992. T. Casey, G. Pritts and B. T. Miller (Tennessee Scientific Study Permit 654). Verified by J. L. Miller. Middle Tennessee State University (MTSU 50A). Second record from Eastern Highland Rim physiographic region of middle Tennessee (Miller and Miller 1992, SSAR Herpetol. Rev. 22:133; Redmond 1985, A Biogeographic Study of Amphibians in Tennessee. Doctoral Thesis, Univ. Tennessee, Knoxville. 290 pp.).

Submitted by **BRIAN T. MILLER**, **TIM CASEY**, and **GARY PRITTS**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog). USA: FLORIDA: Pinellas Co: Largo, jct. Highland Avenue and 5th Avenue NE, ca. 0.48 air km N of Fla. Rt. 686 and ca. 1.9 air km E of Fla. Rt. 651, Sec. 35, T29S, R15E. 8 July 1993. D. M. Crawford and L. A. Somma. Verified by David L. Auth. Florida Museum of Natural History (UF 87694–701). Eight adults collected from trees bordering a pond and from walls of buildings near adjacent parking lot, surrounded by suburban development. Syntopic with active *Hyla cinerea*. County record; extends range in Florida ca. 109 air km N of nearest Gulf coast record in Sarasota County, and ca. 152 air km WSW of northernmost records of inland populations in Orange and Seminole Counties (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part Three. The Amphibians. Windward Publishing, Miami, 191 pp.; unpubl. museum records UF 87341 through 87344). Moreover, these specimens help substantiate an unverified literature record for Pinellas County in nearby St. Petersberg (Carmichael and Williams 1991, Florida's Fabulous Reptiles and Amphibians. World Publications, Tampa, Florida. 120 pp.). Current U.S. distribution of this rapidly spreading Caribbean frog includes Florida's east coast from Dade County north to Indian River County and Florida's Gulf coast from the Florida Keys, Monroe County, north to Sarasota County, an isolated inland record in Glades County, and Puerto Rico and St. Croix (Duellman and Crombie 1970, Cat. Amer. Amphib. Rept. 92:1–2; Wilson and Porras 1983, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9:1–89; Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed., Houghton Mifflin Co, Boston, Massachusetts. 450 pp.)

Submitted by **LOUIS A. SOMMA**, Department of Zoology, University of Florida, Gainesville, Florida, 32611 USA, and **DANIEL M. CRAWFORD**, 13521-120th Lane North, Largo, Florida 34648 USA.

PSEUDACRIS TRISERIATA (Western Chorus Frog). USA: COLORADO: San Juan Co: Columbine Ranger Station, Sec. 13, T39N, R9W, 2693 m. 13 May 1966. A. W. Spencer. National Ecology Research Center, Ft. Collins, Colorado (BS/FC 857); Deer Creek, Sec. 21, T40N, R8W, 2963 m. 13 May 1966. A. W. Spencer (BS/FC 729–767). Verified by Stephen Corn. New county record (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife, Denver. 131 pp.).

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, **GEOFFREY A. HAMMERSON**, Nature Conservancy, 201 Devonshire Street, Boston, Massachusetts 02110, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, and **CINDY RAMOTNIK**, U.S. Fish and Wildlife Service, National Ecology Research Center, 4512 McMurry Avenue, Ft. Collins, Colorado 80525-3400, USA.

RANA PIPIENS (Northern Leopard Frog). USA: COLORADO: Bent Co: Arkansas River, 130 km E Pueblo. 21 August 1947. B. N. Horstman. National Ecology Research Center, Ft. Collins, Colorado (BS/FC 3835, 3837, 3839–40, 3842, 3844); Yuma Co: 19.4 and 32.2 km S Holyoke. 4 October 1967. David Pettus and Douglas D. Post (BS/FC 5466–8). The Bent County record is the southeasternmost in the state and suggests occurrence of the species in Crowley and Otero counties, which lie between Bent and Pueblo counties where it is already known. The Bent County record lies well within the almost exclusive range of *Rana blairi* (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife, Denver, pp. 37, 40), but sympatry is already known in Colorado at several localities farther north and west. Indeed the present series is accompanied from the same locality by nine *R. blairi* (BS/FC 3472–3, 3836, 3838, 3841, 3843, 5469–71). Verified by Stephen Corn. New county records (Hammerson 1982, *op. cit.*).

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA, **GEOFFREY A. HAMMERSON**, Nature Conservancy, 201 Devonshire Street, Boston, Massachusetts 02110, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA, and **CINDY RAMOTNIK**, U.S. Fish and Wildlife Service, National Ecology Research Center, 4512 McMurry Avenue, Ft. Collins, Colorado 80525-3400, USA.

RANA PIPIENS (Northern Leopard Frog). USA: COLORADO: Hinsdale Co: Williams Creek State Wildlife Area, adjacent to southwest corner of Williams Creek Reservoir. 15 August 1991. G. A. Hammerson. UCM Herp Slide no. 74. Lake Bed Reservoir, 2.3 km W Williams Creek Reservoir. 15 August 1991. G. A. Hammerson. UCM Herp Slide no. 73. Both identifications verified by Richard L. Holland. First records for county (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver. 131 pp.). Adults and newly metamorphosed young were present at both sites.

GEOFFREY A. HAMMERSON, The Nature Conservancy, 201 Devonshire Street, Boston, Massachusetts 02110, and **HOBART M. SMITH**, Department of EPO Biology and Museum, University of Colorado, Boulder, Colorado 80308-0334, USA.

SCAPHIOPUS HOLBROOKII (Eastern Spadefoot). USA: FLORIDA: DeSoto Co: SR-70, 2.4 km W of Arcadia. 28 June 1993. W. E. Meshaka, Jr. Verified by J. N. Layne. Vertebrate Collection, Archbold Biological Station (ABS 1178). County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida, Part Three, The Amphibians, Windward Publishing, Miami., Florida).

Submitted by **WALTER E. MESHAKA, JR.**, Archbold Biological Station, P. O. Box 2057, Lake Placid, Florida 33852, USA.

SPEA BOMBIFRONS (Plains Spadefoot). USA: NEBRASKA: Hooker Co: Tucker Ranch, S fork Dismal River. 30 June 1993. Carl E. Bock and H. M. Smith. Verified by David Chiszar. UCM 56789 (5 tadpoles). County record (Lynch 1985. Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **HOBART M. SMITH, CARL E. BOCK**, and **JANE H. BOCK**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

TESTUDINES

CHRYSEMYS PICTA BELLII (Western Painted Turtle). USA: SOUTH DAKOTA: Ziebach Co: Bald Eagle Ranch, 16 km E Howes. 31 May 1992. R. Bald Eagle & D. Chiszar. Verified by Todd Gleeson. UCM 56573–4. County record (Fishbeck and Underhill 1959. Proc. South Dakota Acad. Sci. 38:107–113).

Submitted by **DAVID CHISZAR**, Department of Psychology, and **HOBART M. SMITH**, Department of EPO Biology, both Museum of Natural History, University of Colorado, Boulder, Colorado 80309-0345 and 0344, USA.

CLEMMYS MUHLENBERGII (Bog Turtle). USA: NORTH CAROLINA: McDowell Co: 16 km SSE Marion. R. E. Weaver, Jr. Verified by A. L. Braswell. NCSM 93-7-8 (NCSM photo voucher DWH 93.09). New county record and first for Broad River drainage. Extends range 37 km SE nearest Blue Ridge province record in Yancey County (Herman 1986, Herpetol. Rev. 17(2):50) and 74.4 km NW nearest Piedmont record in Gaston County (Herman et al. 1992, Herpetol. Rev. 23(4):122).

Submitted by **DENNIS W. HERMAN**, Zoo Atlanta, 800 Cherokee Ave. SE, Atlanta, Georgia 30315, **BERN W. TRYON**, Knoxville Zoological Gardens, P. O. 6040, Knoxville, Tennessee 37914, and **ALLEN C. BOYNTON**, North Carolina Wildlife Resources Commission, 209 Ervin Road, Morganton, North Carolina 28655, USA.

KINOSTERNON SUBRUBRUM SUBRUBRUM (Eastern Mud Turtle). USA: NORTH CAROLINA: Rutherford Co: 15.1 km N Rutherfordton. D. W. Herman and A. C. Boynton. Verified by A. L. Braswell. NCSM 93-7-8 (NCSM photo voucher DWH 93.01A). New county record and westernmost record for the state. Extends range 26.7 km SW nearest Burke Co. record (NCSM files).

Submitted by **DENNIS W. HERMAN**, Zoo Atlanta, 800 Cherokee Ave. SE, Atlanta, Georgia 30315, and **ALLEN C. BOYNTON**, North Carolina Wildlife Resources Commission, 209 Ervin Road, Morganton, North Carolina 28655, USA.

STERNOTHERUS MINOR PELTIFER (Stripeneck Musk Turtle). USA: MISSISSIPPI: Tishomingo Co: Bear Creek at county road bridge ca. 3.2 km ENE Dennis. NE 1/4, NE 1/4, NE 1/4, Sec. 13, T6S, R10E. 18 August 1993. R. L. Jones, C. Knight, T. Majure. Verified by Terry L. Vandeventer. Mississippi Museum of Natural Science (MMNS 2021). First record from Tennessee River drainage of northeastern Mississippi (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.); extends range ca. 50 km SW of nearest Tennessee River tributary record in Alabama (Iverson 1977, Copeia 1977:502–517).

Submitted by **R. L. JONES, CHARLES KNIGHT**, and **TERRY MAJURE**, Mississippi Department of Wildlife, Fisheries, and Parks, Museum of Natural Science, 111 North Jefferson Street, Jackson, Mississippi 39201, USA.

LACERTILIA

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). USA: NEBRASKA: Nuckolls Co: Angus, T4N, R6W, Sect. 27. 16 September 1931. L. T. Barry. Verified by Stephen Corn. USFWS National Ecology Research Center (Ft. Collins, Colorado) BS/FC 3210. First county record (Lynch 1985, Trans. Nebraska Acad. Sci., 13:42).

Submitted by **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, **HOBART M. SMITH**, Department of EPO Biology, Univ. Colorado, Boulder, Colorado 80309-0334, and **CINDY RAMOTNIK**, U.S. Fish and Wildlife Service, National Ecology Research Center, 4512 McMurry Avenue, Ft. Collins, Colorado 80525-3400, USA.

EUMECES MULTIVIRGATUS MULTIVIRGATUS (Northern Many-lined Skink). USA: COLORADO: Logan Co: Tamarack Ranch Wildlife Area, 4.9 km S Crook. 18 May 1982. E. L. Smith and J. F. Ellis. National Ecology Research Center, Ft. Collins, Colorado (BS/FC 2345). Verified by Stephen Corn. New county record (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife, Denver. 131 pp.).

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA, **GEOFFREY A. HAMMERSON**, Nature Conservancy, 201 Devonshire Street, Boston, Massachusetts 02110, USA, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA, and **CINDY RAMOTNIK**, U.S. Fish and Wildlife Service, National Ecology Research Center, 4512 McMurry Avenue, Ft. Collins, Colorado 80525-3400, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: LOUISIANA: Ouachita Parish: West Monroe, department store on Thomas Avenue, 1.2 road km N I-20. 8 May 1992. S. G. George, et al. Northeast Louisiana University Museum of Zoology (NLU 70468); Hanna Hall Geoscience Building on Northeast Louisiana University campus, University Avenue, 0.5 road km W of Rt. 165. 25 September 1992. S. L. Jensen. NLU 70470. Both specimens verified by Neil H. Douglas. New parish records; extends the range ca. 250 road km north of prior records in Louisiana. (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press, Baton Rouge. 300 pp.).

Submitted by **STEVE L. JENSEN** and **STEVEN G. GEORGE**, Department of Biology, Northeast Louisiana University, Monroe, Louisiana 71209, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: NEVADA: Clark Co: Las Vegas, NW 1/4 Sec. 1, T20S, R61E.

Breeding population of 12 adults (5 males, 7 females) and 2 juveniles (1 male, 1 female) collected in a trailer park. 3 October 1992. Mary B. Saethre. Verified by John W. Wright. LACM 140328–140341. State record; first known locality in Nevada, and extends known range ca. 370 km NW nearest known localities in Phoenix-Tempe, Maricopa County, Arizona (Robinson and Romack 1973, J. Herpetol. 7(3):311–312), 392 km N Ocotillo, Imperial County, California (LACM 137493–137495; Porter 1988, San Diego Herpetol. Soc. Newsletter 10:5), and 390 km N El Centro, Imperial County, California (Laudenslayer et al. 1991, Calif. Fish and Game 77(3):109–141; W. F. Laudenslayer, Jr., pers. comm.). Establishment of the species in Las Vegas is not surprising; it appears to be dispersed via travelers and Las Vegas has a high volume of traffic moving through the area. These lizards were found in a long-standing trailer park (>30 years), and the population is likely to have been in this area for a number of years.

Submitted by **MARY B. SAETHRE**, University of California at Los Angeles, Laboratory of Biomedical and Environmental Sciences, P. O. Box 495, Mercury, Nevada 89023, USA, and **PHILIP A. MEDICA**, Natural History Museum of Los Angeles County, Section of Herpetology, 900 Exposition Boulevard, Los Angeles, California 90007, USA.

HOLBROOKIA M. MACULATA (Northern Earless Lizard). USA: NEBRASKA: Box Butte Co: Running Water (= Niobrara River) Quarry, S Marsland. No date. No collector. Verified by Richard L. Holland. UCM 50529. First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:43).

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, and **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA.

PHRYNOSOMA SOLARE (Regal Horned Lizard). USA: NEW MEXICO: Hidalgo Co: Guadalupe Canyon, pitfall trap in canyon bottom 0.16 road km NNE of NM/AZ border and ca. 53 air km S Rodeo, Sec. 14, T34S, R22W. 25 June 1993. Barney R. Tomberlin. Verified by Wade C. Sherbrooke. University of New Mexico Museum of Southwestern Biology (MSB 55920). New state record.

Submitted by **CHARLES W. PAINTER**, Endangered Species Program, New Mexico Department of Game and Fish, P. O. Box 25112, Santa Fe, New Mexico 87504, USA.

SCELOPORUS SERRIFER CYANOGENYS (Blue Spiny Lizard). MEXICO: COAHUILA: Municipality of Guerrero: Misión San Bernardo at Guerrero on México Hwy. 2, 300 m elev. 9 May 1988. Ernest A. Liner, Richard R. Montanucci, Arturo González Alonso, and Fernando Mendoza Quijano. Museo de Zoología, Facultad de Ciencias, UNAM. MZFC 5849, male, 127.5 mm SVL, broken tail. Verified by Oscar Flores-Villela. Found on the walls of the Misión. First record for the state but was to be expected since it has been recorded from nearby localities in Texas. A specimen (TCWC 54448) listed by Olson (1989, Bull. Maryland Herpetol. Soc. 23:158–167) as from 3 mi S Sabinas Hidalgo, Hwy 85, Coahuila, is actually located in Nuevo León.

Submitted by **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, UNAM, Apdo. Postal 70-399, D. F. 04510, México, **ERNEST A. LINER**, 310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA, **RICHARD R. MONTANUCCI**, Department of Biological Sciences, College of Science, 132 Long Hall, Clemson University, Clemson, South Carolina 29634-1903, USA, and **ARTURO GONZALEZ ALONSO**, San Marcos 79, San Marcos Azcapotzalco, D. F. 020202, México.

SCELOPORUS UNDULATUS ERYTHROCHEILUS (Red-lipped Plateau Lizard). USA: COLORADO: Teller Co: Mueller State Park, 0.5 km W Sand Burr Mine, Dome Rock Trail. 19 July 1993. Russell P. DeFusco. Verified by Richard L. Holland. UCM 56792. First county record (Hammerson 1986, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife, Denver. 131 pp.); westernmost range limit in that area where it is rare; found in crevice in granite boulders (no preferred sandstone in vicinity).

Submitted by **RUSSELL P. DEFUSCO**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

SCELOPORUS UNDULATUS GARMANI (Northern Prairie Lizard). USA: COLORADO: Adams Co: Bijou Creek, 2 km S Hoyt. 5 August 1993. Richard L. Holland and H. M. Smith. Verified by David Chiszar. UCM 56795. First county record (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, Denver. 131 pp.), southernmost known locality in the South Platte River drainage; in Adams County apparently limited to Bijou Creek.

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, and **HOBART M. SMITH**, Department of EPO Biology and Museum, University of Colorado, Boulder, Colorado 80309-0334, USA.

SCELOPORUS UNDULATUS GARMANI (Northern Prairie Lizard). USA: NEBRASKA: Box Butte Co: 8 km E & 8 km S Alliance. 1 July 1993. Royce E. Ballinger, Brian R. Roh, Kristin S. Bird and Hobart M. Smith. UCM 56790. Verified by David Chiszar. First county record (Lynch 1985, Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **ROYCE E. BALLINGER**, School of Life Sciences, University of Nebraska, Lincoln, Nebraska 68588-0118, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

SERPENTES

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer). USA: NEBRASKA: Gosper Co: 8 km N Elwood. 29 June 1993. H. M. Smith. UCM 56787; Hayes Co: 16 km NE Hayes Center. 29 June 1993. H. M. Smith. UCM 56788. Both verified by David Chiszar. County record (Lynch 1985. Trans. Nebraska Acad. Sci. 13:33–57).

Submitted by **HOBART M. SMITH**, **CARL E. BOCK**, and **JANE H. BOCK**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

COLUBER CONSTRICTOR FLAVIVENTRIS (Eastern Yellowbelly Racer). USA: SOUTH DAKOTA: Ziebach Co: near village of Cherry Creek at confluence of Cherry Creek and Cheyenne River. 31 May 1992. D. Chiszar. Verified by Todd Gleeson. UCM 56571. County record (Fishbeck and Underhill 1959. Proc. South Dakota Acad. Sci. 38:107–113).

Submitted by **DAVID CHISZAR**, Department of Psychology, and **HOBART M. SMITH**, Department of EPO Biology, both Museum of Natural History, University of Colorado, Boulder, Colorado 80309-0345 and 0344, USA.

CROTALUS ATROX (Western Diamondback Rattlesnake). USA: ARKANSAS: Conway Co: SW 1/4 NW 1/4 Sec. 1, T5N, R19W. 11 June 1992. Steve Austin and Christine Austin. Verified by J. T. Collins. KU 220925 (skin only; large adult). New county record.

Submitted by **GLYN TURNIPSEED**, Department of Biology, Arkansas Tech University, Russellville, Arkansas 72801, USA.

CROTALUS TIGRIS (Tiger Rattlesnake). USA: ARIZONA: Cochise Co: AOR along a gravel road into Guadalupe Canyon, ca. 5.6 air km W Arizona/New Mexico state line and ca. 47 air km E

Douglas, Sec. 17, T24S R32E. 11 August 1993. Chris Milensky and Darrell James. University of New Mexico Museum of Southwestern Biology (MSB 56030). Verified by James N. Stuart. First county record and extends range ca. 138 km to the east (C. H. Lowe Jr. pers. comm.; Lowe et al. 1986, Venomous Reptiles of Arizona. Publ. Arizona Game and Fish Dept., Phoenix. 115 pp.)

Submitted by **CHARLES W. PAINTER**, Endangered Species Program, New Mexico Department of Game and Fish, Santa Fe, New Mexico 87504, USA, and **CHRISTOPHER M. MILENSKY**, 1955 East Colorado #24, Las Cruces, New Mexico 88001, USA.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). USA: COLORADO: Phillips Co: Amherst. October 1977. Landreth. National Ecology Research Center, Ft. Collins, Colorado (BS/FC 2436–65). Verified by Stephen Corn. New county record (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Div. Wildlife, Denver. 131 pp.).

Submitted by **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA, **GEOFFREY A. REGINA RIGIDA (Glossy Crayfish Snake). USA: VIRGINIA: New Kent Co: Diascund Creek, tributary to the Chickahominy River, 3.2 km SW Lanexa. 29 April 1991. K. A. Buhlmann. Verified by G. R. Zug. USNM 327174. This juvenile was found buried in detritus of a muskrat house at the edge of a freshwater tidal marsh. A second juvenile was captured in the same marsh on 4 April 1992 by A. H. Savitsky and B. A. Savitsky in a crayfish burrow under several pieces of bark. This individual was photographed and released; photographs (AHS-FS 954) are in the possession of A. H. Savitsky, Old Dominion University. Two juvenile glossy crayfish snakes representing the first Virginia records were collected from Diascund Creek on 28 October 1939 (Richmond 1940, Herpetologica 2:21; CM 18171, CM 18172). Five others were found by N. D. Richmond in February and March 1940 (CM 18531, 18862-65). This species was not collected again until 1991 despite several herpetological forays in the 1980s. It has yet to be found elsewhere in Virginia. The nearest North Carolina records are 190 km SE in Manns Harbor, Dare County (L. Palmer and A. Braswell, pers. comm). The recent collections confirm *R. rigida* as a member of Virginia's herpetofauna and suggest that further inventory of

other freshwater tidal marshes in southeastern Virginia is warranted.

New Distributional Records Of Amphibians And Reptiles For The State Of Falcón, Venezuela

As part of our activities at the Centro de Investigaciones en Ecología y Zonas Aridas (CIEZA), of the Universidad Francisco de Miranda, Coro, Venezuela, we surveyed the herpetofauna of the state of Falcón. Field work and examination of catalogs in important Venezuelan museums have yielded a series of first records for this state. Specimens reported are deposited in the Museo de Historia Natural La Salle, Caracas (MHNLS), Museo de Ciencias Naturales de Caracas, Caracas (MCNC), Museo de Ciencias Naturales de Guanare, Guanare (MCNG), and Estación Biológica de Rancho Grande, Maracay (EBRG).

ANURA

CERATOPHRYS CALCARATA. Distrito. Silva: Sanare. 1 December 1984. EBRG 1407; 18 October 1985. EBRG 1515; 22 October 1985. EBRG 1516. All collected by R. A. Rivero and I. Rivero. Identified by R. A. Rivero. Easternmost record for Venezuela (La Marca 1992).

ELACHISTOCLEIS OVALIS. Distrito. Silva: Palma Sola-Boca de Aroa Hwy, Finca El Sixcom, 20 m. 6 July 1968. Collected by J. Joly and J. L. Garcia. Identified by J. M. Peláez. MHNLS 3472. Northeasternmost record in Venezuela (La Marca 1992).

HYLA MINUTA. Distrito. Colina: 13.0 km (by road) from Dos Bocas via Pueblo Nuevo de la Sierra, Sierra de San Luis, ca. 410 m. 7 August 1992. Collected by A. Mijares, J.-M. Hero and F. Sánchez. Identified by J.-M. Hero. MCNG 2180-82. Northwesternmost record for the species in Venezuela (La Marca 1992).

FLECTONOTUS PYGMAEUS. Distrito. Petit: Curimagua. 20 December 1957. Collected by E. Valladares. Identified by Juan A. Rivero. MHNLS 1512. Westernmost record in Venezuela (La Marca 1992).

PHYLLOMEDUSA TRINITATIS. Distrito. Petit: Curimagua. 19 December 1957. Collector unregistered. Identified by Juan A. Rivero. MHNLS 1503. Westernmost record in Venezuela (La Marca 1992).

AMPHISBAENIA

AMPHISBAENA FULIGINOSA. Distrito. Acosta: Las Lapas. September 1968 (specific date not given). Collected by L. Duque. Identified by A. R. Lancini. MCNC 5183.

LACERTILIA

ANOLIS AURATUS. Distrito. Mauroa: Mene de Mauroa. July 1968 (specific date not given). Collected by Pedro Ricardi. Identified by E. E. Williams. MCNC 4115, 4118, 4126. First definite record for the state, although previously reported as in "Venezuela" by Peters and Donoso-Barros (1970) and Hoogmoed (1973).

BASILISCUS BASILISCUS BARBOURI. Distrito. Acosta: Río Tocuyo (Boca de Tocuyo). 11 February 1984. Collected by G. Cordero. Identified by R. A. Rivero. EBRG 1738. Northeasternmost record in Venezuela (Lancini 1980).

SERPENTES

MICRURUS MIPARTITUS SEMIPARTITUS. Distrito. Silva: Sanare. 21 July 1984. Collected and identified by R. A. Rivero.

EBRG 1791. Northeasternmost record in Venezuela (Lancini 1979; Roze 1966).

Acknowledgments.—We thank those who gave us access to museum specimens and/or catalogs: Francisco Bisbal and Ramón Rivero (EBRG), María J. Praderio and J. Celsa Señaris (MHNLS), Pedro Delgado (MCNC), and Pedro Pacheco (MCNG). Enrique La Marca provided helpful criticism on an earlier draft of this manuscript. Partial financial support was provided by grant No S1–9112–030 from the Fundación para el Desarrollo de la Ciencia y la Tecnología del Estado Falcón.

1994 Chicago Herpetological Society Grants Program

The Chicago Herpetological Society announces the CHS Herpetological Grants program to award financial support for herpetological research, education, and conservation. Four awards of up to $500 each will be available. Interested parties may apply for a grant in any one of the following categories: 1) Illinois herpetology; 2) Graduate Student Research in Herpetology; 3) Field Studies in Herpetology; 4) Conservation; 5) Captive Management, Husbandry, and Propagation.

Applicants must be CHS members. In accepting a grant, the recipient agrees to abide by all state and federal laws, to submit a written summary at the end of their work for publication in the CHS *Bulletin*, and to acknowledge the CHS in any publications that result from their subsidized research. Recipients are encouraged to submit their work in article form or as a CHS monthly meeting program.

Applications should include the following: 1) statement of proposal objectives; 2) description of materials and methods; 3) complete budget, not to exceed $500; 4) brief resume of the applicant, if an individual. If the applicant is an organization, background information on the organization should be included. 5) A completion date for the project.

Applications must be typed, double-spaced, with four copies submitted. Applications should be kept brief; proposals longer than four pages are discouraged. All applications must be received by 1 March 1994, and awards will be announced by 1 May 1994.

It is the goal of the Grants Committee to award grants to a variety of applicants; enthusiastic amateurs will receive equal consideration with professional herpetologists and graduate students. Topics including Illinois herpetology, captive husbandry and propagation, and those which may translate into quality CHS *Bulletin* articles or monthly meeting programs are favored, though not requisite.

Submit applications to: *CHS Herpetological Grants, Chicago Herpetological Society, 2001 North Clark Street, Chicago, Illinois 60614, USA.*

An Annotated List Of The Reptiles And Amphibians Of Macau, Southeast Asia

The herpetological fauna in Macau would be expected to be somewhat similar to that found in the neighboring British colony of Hong Kong which is located just 40 km away across the Pearl River estuary. Assuming that Hong Kong as well as Macau lie in an intermediate zone between the Oriental and the Palearctic faunal regions (Hill and Phillipps 1981), both Hong Kong and Macau should possess a mixed fauna with elements from both regions. Geographically like Hong Kong, Macau consists of a peninsular land area connected to the Guangdong Province of mainland China as well as islands. Macau has only two islands—Taipa (113°35'N, 22°10'E) and Coloane (113°33'N, 22°08'E)—which are connected to the mainland by either a road bridge or a causeway. Despite this connection there appears to be little faunal interchange. Habitats for herps on the mainland peninsula are under threat due to the recent urbanization in Macau as well as in other areas of Southeast Asia, and aquatic habitats on the islands are also dwindling in size.

Material reported in this study was largely collected between 1989 and 1992 from the islands of Taipa and Coloane and the Guia light house forested hill area on the Macau peninsula. Records are also included from a small collection of herps maintained at the CMI Agriculture and Forestry center on Coloane (Leung-Va 1991). Identifications of the local fauna were made with the aid of color plates found in Karsen et al. (1986), and representative specimens deposited in the Bernice P. Bishop Museum (BBM) in Honolulu, Hawaii have been identified by J. D. Lazell.

The fauna of Hong Kong is much better known than that of Macau largely due to the efforts of Romer (1975, 1979a, 1979b) as recently reviewed by Lazell (1988). Due to geographic isolation the fauna of Macau is not identical with that of Hong Kong and we here report a number of new distributional records.

AMPHIBIA

BUFO MELANOSTICTUS Schneider. Asian Common Toad. BBM 11654 found 2 June 1990, BBM 11654 and 11655 in August 1989, and BBM 11656 on 4 June 1990 (E. Easton leg.). Commonly observed foraging at night under street lamps in Coloane village, Coloane Island, and likely the most common amphibian in Macau. Serves as food for numerous serpents; three individuals were observed regurgitated from a disturbed *Ptyas mucosus* on Taipa island. Eggs and tadpoles are common during early summer in roadside gutters that fill with water. Metamorphosis occurs in less than one week in ±1.0 cm individuals that leave the water.

RHACOPHORUS (POLYPEDATES) LEUCOMYSTAX (Gravenhorst). Brown Treefrog. BBM 11648 and 11649 found on 27 June 1990; BBM 11650 is a foam nest with many hatched tadpoles found on 30 May 1990 (E. Easton leg.). This frog has been observed resting on horizontal branches of the horsetail tree at heights of 3 m on the islands of Taipa and Coloane. Foam nests have been observed in cement cisterns partially filled with water near a construction site on the university campus and attached to the upper edges of road culverts during spring and early summer.

RANA LIMNOCHARIS Boie. Paddy Frog. BBM 11651 and 11652 found 19 June 1990 (E. Easton leg.) and 14 August 1991 at Guia Hill (E. Easton and G. Ades leg.). A common frog observed in freshwater ponds on both Taipa and Coloane islands.

RANA GUENTHERI Boulenger. Günther's Frog. Found 17 September 1991 in road culvert near Ka-Ho village, Coloane island (E. Easton leg.). Also observed inhabiting a stream flowing through a mine shaft near Choec-van village in August and September.

KALOULA PULCHRA Gray. Asiatic Painted Frog. BBM 11647 found 9 June 1990 on Taipa Island in rain gutter (E. Easton leg.). Commonly seen at night after a rain foraging for food in roadside gutters on Taipa Island. Mating noted on Guia Hill on the Macau peninsula in a water filled ditch near a jogging track. This frog burrows in mud during the drier periods of the year.

MICROHYLA PULCHRA (Hallowell). Marbled Pigmy Frog. BBM 11646 found 27 June 1990 and 19 June 1992 (E. Easton leg.) along roadside at bottom of hill on Taipa Island near cemetary. Frog is seen in low lying areas at night where it crosses roadways.

MICROHYLA ORNATA (Duméril and Bibron). Ornate Pigmy Frog. Found 15 June and 15 July 1991 on Taipa island (E. Easton leg.) in similar locality as *M. pulchra* above.

REPTILIA

GEKKO CHINENSIS Gray. Chinese Gecko. BBM 1163 found 22 September 1989 on Taipa Island; 14 January 1992 near reservoir, Siac Pai Van, Coloane Island (E. Easton leg.).

HEMIDACTYLUS BOWRINGI (Gray). Bowring's Gecko. BBM 11660, 11661, and 11662 found on 2 February 1990, BBM 11659 on 30 May 1989, all on Taipa Island (E. Easton leg.) on walls of buildings associated with the University of Macau.

HEMIDACTYLUS BROOKI Gray. Brook's Gecko. Found June 1991 and 4 January 1992 on stone wall and in drainage ditch near university campus on Taipa Island (E. Easton leg.). First reported by Romer (1978) in Macau from specimens collected by S. J. Karsen near a tourist hotel on the Macau peninsula. Mortality appeared to be high in January 1992 when insect prey was not available and geckos could not enter semi-hibernation.

HEMIDACTYLUS GARNOTI Duméril and Bibron. Indo-Pacific Gecko. Found 5 January 1992 near Tai Fung Building on the University of Macau campus, Taipa Island (E. Easton leg.).

CALOTES VERSICOLOR (Daudin). Crested Tree Lizard. BBM 11657 found on 23 May 1990 (C. J. Lopes leg.) and BBM 11658 in July 1989 (Y. Y. Mei leg.) from Taipa Island. Commonly seen climbing vegetation on both islands of the territory.

LEIOLEPIS REEVESII (Gray). Butterfly Lizard. Female (SVL 10 cm, tail 20 cm) found behind beach at Hac-Sa village on 9 July 1991, Coloane Island (E. Easton and Leung-Va leg.). A small resident population of this species occupies an old field habitat containing numerous underground burrows. Only females have so far been observed, suggesting the species is parthenogenetic. Also observed on Taipa Island (Leung-Va, pers. observ.). This species has not been reported from Hong Kong or from any of its islands (Karsen et al. 1986).

ATEUCHOSAURUS CHINENSIS Gray. Chinese Forest Skink. BBM 11669 found in June 1989 and on 16 June 1991 in rain gutter on Taipa Island near University (E. Easton leg.). Also collected from a park near Siac Pai Van on Coloane Island in summer 1992.

EUMECES QUADRILINEATUS (Blyth). Blue-tailed Skink. BBM 11671 collected on 22 June 1990 in rain road side gutter near University on Taipa island (E. Easton leg.).

SCINCELLA (LEIOLOPISMA) REEVESI (Gray). Reeves' Smooth Skink. BBM 11670 found in June 1989 in rain gutter on Taipa Island (E. Easton leg.). Also noted in forested area near stream at Choec-van on Coloane Island.

PYTHON MOLURUS BIVITTATUS Schlegel. Burmese Python. Specimen with an SVL of 63 cm (tail 10 cm) was found on 7 September 1991 at Estrada Choc-van, Coloane Island; another collected on 22 August 1991 at Hovione Chemical Plant area on Taipa Island (E. Easton leg.).

AMPHIESMA STOLATA (Linnaeus). Buff-striped Keelback. BBM 11674 found August 1989 and BBM 11675 found 17 June 1990, both on Taipa Island near university campus (E. Easton leg.).

BOIGA MULTIMACULATA (Boie). Large-spotted Cat Snake. Specimen with SVL of 55 cm (tail 12 cm) found July 1984 on Coloane Island (Leung-Va leg.). A shed skin of this species was noted along a road side near Hac-sa village during the summer of 1991.

ENHYDRIS BENNETTI (Gray). Mangrove Water Snake. Specimen with an SVL of 29.5 cm (tail 5.0 cm) found on 15 July 1992 at Siac Pai van on reclaimed land near Mangrove, Coloane Island (Leung-Va leg.).

OLIGODON FORMOSANUS (Günther). Taiwan Kukri Snake. Specimen with an SVL of 38 cm (tail 7.5 cm) was found on 27 August 1991 at Estrada da Choec-van, Coloane Island (E. Easton leg.); another collected on 23 May 1990 from a park at Siac Pai Van, Coloane Island (Leung-Va leg.) is believed to be the first record of this uncommon species in Macau.

PTYAS KORROS (Schlegel). Indo-Chinese Rat Snake. BBM 11676 found in October 1989 on Taipa Island on a hillside near the University of Macau campus (E. Easton leg.).
PTYAS MUCOSUS (Linnaeus). Common Rat Snake. BBM 11672 found on 14 October 1989 at Guia hill on Macau peninsula (S. H. Chan and E. Easton leg.). BBM 11673 found on 6 October 1989 on Taipa Island on hillside near university campus (E. Easton leg.).

BUNGARUS M. MULTICINCTUS Blyth. Many-banded Krait. Specimen observed on 21 July 1991 in rain gutter along road side near cemetary on Taipa Island.

NAJA NAJA ATRA (Cantor). Chinese Cobra. On 20 August 1991, two immature specimens were found DOR near university campus on Taipa Island (E. Easton leg.).

RAMPHOTYPHLOPS BRAMINUS (Daudin). Brahminy Blind Snake. BBM (catalog number pending) found in summer 1989 on hill on Taipa Island (identified by A. Allison); SVL's 12.5, 10 (tail lengths 2.0, 1.0); another specimen on 12 September 1991 in a drainage ditch along roadside near Ka-Ho village, Coloane Island (E. Easton leg.).

TRIMERESURUS ALBOLABRIS (Gray). White-lipped Pit Viper. Specimen found on 14 September 1991 along roadside near Choec-van village, Coloane Island (E. Easton leg.).

CHINEMYS REEVESI (Gray). Reeves' Terrapin. From a stream on C-4 Mountain, Coloane Island, during 1981 (Leung-Va leg.). The currrent status of this species in Macau is not known.

CUORA FLAVOMARGINATA (Gray). Yellow-lined Box Terrapin. Specimen with a carapace length of 12.5 cm (plastron 7.4-5.7 cm) found on 21 May 1992 at Siac Pai van in reclaimed area of Coloane Island (Leung-Va leg.).

CUORA TRIFASCIATA (Bell). Three-banded Box Terrapin. This species was last observed in a marshy area near Hac-sa Beach on Coloane Island in 1989. Current status is unknown as it is widely sought for human food and sold in Macau markets.

TRIONYX (PELODISCUS) SINENSIS Wiegnann. Chinese Softshell. Specimen found on 10 April 1992 at Siac Pai van on Coloane Island (Leung-Va leg.). This is a very common species sold in Macau markets; most individuals are probably being imported from mainland China.

Even though Barros (1978) listed four species of Elapidae and one species of hydrophiid sea snake as occurring at one time in Macau we have not been able to determine the current status of *Hydrophis cyanocinctus* (Daudin), *Bungarus fasciatus* (Schneider), and *Ophiophagus hannah* (Cantor), because preserved specimens are not available locally for examination. Mendes et al. (1991) also listed three species of Ranidae as occurring on Macau, according to a zoological survey completed by the zoological institute in Portugal. The third species of ranid may have been *Rana tigrina* because the Chinese bullfrog is commonly sold as human food in Macau markets. Often specimens in the Macau markets are not found locally and such seems to be the case for *Takydromus sexlineatus ocellatus*, a lizard that is commonly sold in pet shops as food for birds, but has not been observed locally and probably is imported from one of the neighboring provinces of mainland China.

Acknowledgments.—The authors wish to thank Father Anthony Bogadek, St. Louis School, Hong Kong for determining the identity of *Leiolepis reevesii* from Macau. This study could not have been made without the cooperation of Mr. Carlos D. C. Batalha, Head of Agrarian Dept., Câmara Municipal das Ilhas, Coloane (Island government, Macau).

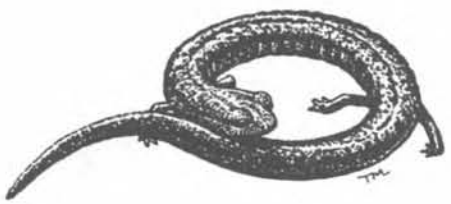
PUBLICATIONS RECEIVED

Guide to the Reptiles and Amphibians of the Savannah River Site by J. Whitfield Gibbons and Raymond D. Semlitsch. 1991. The University of Georgia Press. xii + 131 pp. Hardcover. US $20.00. ISBN 0-8203-1277-0.



Keys and species accounts for the 100 species of amphibians and reptiles found at the Savannah River Site (SRS) near Aiken, South Carolina. The ecological information presented is derived specifically from data on animals on the SRS. Descriptions of particular sites representing all habitat types on the Site are provided. The book also features a bibliography of herpetological reprints of the Savannah River Ecology Lab (indexed by taxon and subject), theses and dissertations based on work at the lab, and general references.

Geographic Variation and Speciation in the Torrent Salamanders of the Genus *Rhyacotriton* (Caudata: Rhyacotritonidae) by David A. Good and David B. Wake. 1992. University of California Publications in Zoology 126. xii + 91 pp. Softcover. US $12. ISBN 0-520-09778-5.

A systematic treatment of torrent salamanders in which two new species are described, another raised from subspecies, and a new family, the Rhyacotritonidae, is erected. Variation in morphometrics, color, life history, osteology, and proteins are discussed in detail and a scenario is presented for the phylogenetic and biogeographic history of these salamanders. Illustrated by numerous maps, line drawings and bivariate plots.

Anfibios y Reptiles en Nuestro Folklore by Juan A. Rivero and Donato Seguí Crespo. Date of publication not stated. Published by Juan A. Rivero. 98 pp. (including 21 color figures, 8 black & white figures). Price to booksellers is US $9.80 + $2 per book insured air mail (minimum order of 3 books); $12 to libraries and individuals (+ $2 shipping). Order directly from Rivero (Box 5121, College Sta. Mayagüez, Puerto Rico 00681, USA). In Spanish.

A detailed look at the natural history of four prominent species of herps in Puerto Rico. The profiled species are the coquí (*Eleutherodactylus coqui*), the crested toad (*Peltophryne lemur*), the giant green anole (*Anolis cuvieri*), and the Puerto Rican boa (*Epicrates inornatus*). Includes poems and musical compositions dedicated to these animals.

Batrachoseps pacificus complex ("Santa Lucia Mts." form). USA: California: Monterey Co., Pacific Grove. Illustration by Tim Manolis.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). ***HR*** especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints.

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc.; 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes, and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of external reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Life History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

RWH

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc. RFD 6 Box 1, Lawrence, Kansas 66046. *Herpetological Review* is composed using Microsoft Word and Aldus Pagemaker on Apple Macintosh computers. Camera-ready copy is produced on a Linotronic 230 Imagesetter at a resolution of 1700 dpi at Valley Type & Design, Fresno, California. All rights reserved. No part of this periodical may be reproduced without written permission of the editor.

SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

Catalogue Of American Amphibians And Reptiles

The catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 530	$200.00
INDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages	$5.00
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$5.00
IMPRINTED POST BINDER: (note - two binders are needed for the 505 accounts)	$25.00
INCOMPLETE SET: NUMBERS 1 - 190	$60.00
191 - 410	$70.00
411 - 530	$75.00

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology***. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1993

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*
Institutional subscription	$60.00		

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired.). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

SSAR BUSINESS

New Section Co-Editors

Jerry Johnson has assumed the section co-editorship for Geographic Distribution effective immediately. He takes over for Darrel Frost who served in this capacity for three years. Darrel's efforts on behalf of *HR* are sincerely appreciated. All non-US, non-Canadian distribution records should be sent to: *Jerry D. Johnson, Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA.*

Lee Fitzgerald is the new section co-editor for Life History Notes. He will handle all manuscripts concerning reptiles, while current section editor Randy Jennings will process those dealing with amphibians. Fitzgerald's address is: *Lee A. Fitzgerald, Department of Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.*

Annual Report (1993) Grants-In-Herpetology Committee

Five awards (of $500 each) in four categories were made this year, as follows:

Graduate Student Research.—Kelly R. Zamudio, Department of Zoology, University of Washington, Seattle. Title: "Female reproductive investment: investigating the trade-offs between current reproduction, survival and growth."

Field Work.—Janna M. Ellingson, Department of Zoology, The University of Texas at Austin. Title: "Sensory systems and selection on male coloration in a diurnal gecko."

Field Work.—Timothy B. Watkins, Department of Ecology and Evolutionary Biology, University of California, Irvine. Title: "Predator-mediated selection on locomotor performance in *Hyla regilla*."

Zoo Research.—J. Kevin Bowler and Ann Weber-Rabin, Audubon Park and Zoological Garden, New Orleans, Louisiana. Title: "Amphibian decline exhibits and education."

Regional Society.—John J. Moriarty, Hennepin Parks, Maple Plain, Minnesota. Title: "Minnesota frog and toad survey, pilot study."

Committee: Dawn S. Wilson (University of South Florida), Anders G. J. Rhodin (Chelonian Research Foundation); Charles W. Painter (New Mexico Department of Game and Fish), Julian C. Lee (University of Miami), Randy Jennings (University of Nevada, Las Vegas), Carole L. Hom (University of California, Davis), Maureen A. Donnelly (University of Miami), A. Dale Belcher (chair, Rio Grande Zoo).

Catalogue Of American Amphibians And Reptiles

The board of the Society for the Study of Amphibians and Reptiles and the editors of the *Catalogue of American Amphibians and Reptiles* wish to publicly acknowledge and thank the following persons for reviewing *Catalogue* accounts: Jonathan A. Campbell, Ronald I. Crombie, Brian I. Crother, David E. Darda, Oscar Flores-Villela, Orlando H. Garrido, Robert W. Henderson, John B. Iverson, J. Eric Juterbock, William W. Lamar, James R. McCranie, John S. Mecham, James E. Platz, Gregory K. Pregill, Douglas A. Rossman, Michael E. Seidel, Richard Thomas, Stephen G. Tilley, Jaime D. Villa, David B. Wake, and Ernest E. Williams.

Catalogue Erratum

Some copies of account number 546, *Rhadinaea godmani*, in the *Catalogue of American Amphibians and Reptiles* were inadvertently sent out in error (pages 2-3 were from account number 539, *Amphisbaena gonavensis*). Correct copies of account number 546 will be mailed with 1993 subscriptions.

C. J. McCoy

Dr. Clarence J. (Jack) McCoy, Curator of the Section of Amphibians and Reptiles at the Carnegie Museum of Natural History, and a Past President of SSAR, passed away on 7 July 1993. An endowment has been established in Jack's name. Contributions earmarked for this fund may be sent to the *Office of the Director, The Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, Pennsylvania 15213, USA.* For more information please contact Mary Ann Schmidt at the Museum, (412) 622–3287. An obituary will appear in a forthcoming issue of *HR*.

NEWSNOTES

Chelonian Research Foundation Linnaeus Fund — 1992 Grant Recipients

The Chelonian Research Foundation (CRF), established as a 501(c)(3) nonprofit private operating foundation in 1992, awarded four grants of $500 each for turtle research through its Linnaeus Fund endowment program on 16 December 1992. Awards granted were as follows:

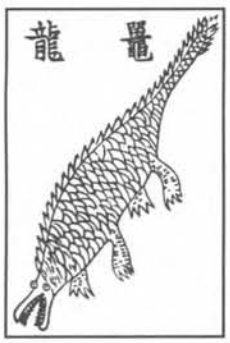
Frye, Sheila E., Antioch New England Graduate School, Concord, New Hampshire. — The ecology and natural history of the wood turtle (*Clemmys insculpta*) in southern New Hampshire.

Janzen, Fredric J., University of California, Davis, California. — Molecular systematics and evolution of sex-determining mechanisms in marsh turtles (*Clemmys*).

Perillo, Kathy, University of New Haven, New Haven, Connecticut. — Seasonal movements and habitat preference of spotted turtles (*Clemmys guttata*) in southern New England.

Webb, Robert G., University of Texas, El Paso, Texas. — Geographic variation in the giant softshell turtle, *Pelochelys bibroni* (Owen).

Linnaeus Fund awards are granted annually to individuals for specific turtle research projects, with either partial or full support as funding allows. Priority is given to projects concerning freshwater turtles, but tortoise and marine turtle research proposals are also considered. Priority is given sequentially to the following general research areas: Taxonomy and Systematic Relationships, Distribution and Zoogeography, Morphology, Ecology and Natural History, and Other Turtle Research. Priority is also given to projects that demonstrate potential relevance to the scientific basis and understanding of Chelonian Diversity and Conservation Biology. Award recipients agree to publish at least partial or summarized results of supported research in a CRF-sponsored publication.



Awards for 1993 are expected to be in the range of five hundred dollars each, hopefully with increasing grant support as the endowment grows. The annual application deadline is 15 November, with annual disbursement prior to 31 December. Submit applications in grant proposal format: title page, project objective, background and research rationale, methods, materials, total project expenses, funding requested from CRF, funding available or requested from other organizations, general timetable, bibliography, and curriculum vitae for all key personnel. Awards will be granted through a review process carried out by the Director and members of the Scientific Advisory Board of CRF. Submit proposals to: ***Chelonian Research Foundation**, Anders G. J. Rhodin, M.D., Director, 168 Goodrich Street, Lunenburg, Massachusetts 01462, USA.*

A New, Extensively Color-Illustrated Book from SSAR

HERPETOLOGY OF CHINA

by Er-mi Zhao and Kraig Adler

•

CHINA, WITH 661 SPECIES OF AMphibians and reptiles in 164 genera and 34 families, possesses one of the largest and most diverse herpetofaunas of any country, and it occupies a strategic geographic position, as it bridges the Oriental and Palaearctic biogeographic zones. Despite the size and relative importance of China's herpetofauna, however, there is no existing work—in Chinese or in any other language—that comprehensively reviews all recognized species, until now.

The purpose of this new, 500-page book, written in English by Er-mi Zhao (Chengdu Institute of Biology) and Kraig Adler (Cornell University), is to summarize the current taxonomic status and distribution of all Chinese species. The geographic coverage includes all of mainland China, plus Macao, Hong Kong, Hainan, and Taiwan.

Table of Contents

History of Herpetological Studies in China

Illustrated Keys to Chinese Amphibians and Reptiles

Annotated Checklist of Genera, Species, and Subspecies (including synonymies)

Distribution of Chinese Amphibians and Reptiles (including charts of distribution by province)

Annotated Bibliography (containing 1825 references)

Appendices (gazetteer of localities; collecting and preserving techniques; Chinese herpetological journals)

Indices to Names of Authors and to Scientific Names

The book contains **48 COLOR PLATES** (371 individual photographs of animals and habitats), *including all genera and 330 species*. Due to the high cost of producing extensively color-illustrated works, this book will be issued in a relatively small edition, a significant part of which is destined for scientists and libraries in China and East Asia.

Specifications: 505 pages, 1 color frontispiece, 72 portraits of herpetologists, 14 other photographs, 24 charts of species distribution, 30 text figures, 4 maps (1 foldout), and 48 color plates. Clothbound in library-grade buckram, 7 x 10–inch format (18 x 25.5 cm). *To be published November 1993.*

ALSO AVAILABLE:

ALLIGATORS IN CHINA, BY A.-A. FAUVEL

A facsimile reprint of the original description of the Chinese alligator (*Alligator sinensis*), published privately in Shanghai in 1879. Includes classical history and legends, natural history, technical description, and literature review. 42 pages, 3 plates, 6 x 9–inch format (15 x 23 cm).

Send Orders To: SSAR Publications Secretary, Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103, USA (*telephone* 314-658-3900 or -3916; *fax* 314-658-3117). Make checks payable to "SSAR"; receipt sent on request only. Overseas orders must be paid in USA funds. Orders may be charged to MasterCard or VISA (account number and expiration date required); a 6.1% bank charge will be added. Price list of SSAR publications and membership application available on request.

ZHAO AND ADLER: HERPETOLOGY OF CHINA

- Price to SSAR members before 1 November 1993. .$50
- Price to Institutions and Non-members $60

(*Postage*: Add $2 in USA, add $4 for other countries.)

FAUVEL: ALLIGATORS IN CHINA

- Single booklet, postpaid (worldwide) $6

HERPFAUN

HERPFAUN is a taxon and faunal unit cross-referenced bibliography of publications concerning the geographical distribution of reptiles and amphibians. It includes faunal monographs, checklists, determination keys, taxonomic revisions, bibliographies, conservation status reports, field guides, etc.—any kind of publication that provides information relevant to the study of area-specific faunas.

The coverage is worldwide; it is not intended to be exhaustive, but does make an especial effort to include more recent publications. The bibliography is available as a pair of 5.25-inch floppy diskettes plus instructions for a limited time only for $5 from: *Dr. Charles H. Smith, 331 Devonshire Street, Apt. D-8, Pittsburgh, Pennsylvania 15213, USA.*

MEETINGS

2nd Annual International Reptile Breeders Convention

The International Reptile Breeders Convention will be held 2-3 October 1993 at the San Diego Concourse, Plaza Hall, in San Diego, California. Speakers and topics include *Husbandry of Gray-banded Kingsnakes* (Bob Applegate), *Breeding Rosy Boas* (Brendan McGraw), *Care, Maintenance & Breeding of Turtles & Tortoises* (Jeff Gee), *Care, Maintenance & Reproductive Husbandry of Gila Monsters & Beaded Lizards* (Bob Applegate), *Panel Discussion on Varanids and Husbandry of Large Lizards* (Robert Sprackland, Mark Bayless, Rick Abrahams).

For further information contact: *IRBA, P.O. Box 85152-279, San Diego, California 92186. Tel. (800) 497-3550, FAX (619) 295-7129.*

LEGISLATION & CONSERVATION ALERT

Call for information on the status of amphibians and reptiles.—This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered herps. We are in need of more information especially on the State and Province level. Please send pertinent information to the Section Editor.

French West Indies: Since 1989, all herpetofauna has been protected in the French West Indies (Guadeloupe, Grande Terre, Desirade, Marie-Galante, Les Saintes, Martinique, Saint-Martin, SaintBarthelemy, and the cays around all these islands). This protection law was published in the Journal Officiel de la Republique francaise (24 March 1989). Scientists who wish to conduct field studies or collect must apply for a permit in which they justify their research and specify the number of animals to be collected. Write to: Direction de la Nature et des Paysages, Ministere de l'Environnement, 14 avenue du General Leclerc, F-92524 Neuilly-sur-Seine. Collection of specimens in the Parc national de la Guadeloupe also requires a permit from the park. Write to: *Monsieur l'attache scientifique, Parc national de la Guadeloupe, Habitation Beau Soleil, Monteran, F-97120 Saint-Claude. This information was supplied by Dr. Michel Breuil, Museum National d'Histoire Naturelle, 25, rue Cuvier - 75005 Paris.*

A Request for Information on Rattlesnake Commercialization: There is an unquantified and unregulated commercial trade in rattlesnakes. Snakes from rattlesnake roundups apparently account for less than half of the snakes entering the trade. A study funded by TRAFFIC USA/World Wildlife Fund has been initiated to evaluate the extent of rattlesnake commercialization for whole animals and parts. The researchers would appreciate any information regarding: what parts are sold; the origin and species of snakes used; the prices and types of items; and the addresses of the businesses selling these products. Herpetologists can gather information at curio shops, "tourist traps," mall stores, boot and leather dealers, etc. This information will be used to formulate conservation strategies aimed at preserving rattlesnake populations. Send information to: *Charles W. Painter and Lee A. Fitzgerald, Museum of Southwestern Biology, Biology Department, University of New Mexico, Albuquerque, New Mexico 87131, USA. FAX: (505) 277-0304.*

Amphibian Decline Newsletter

The *Froglog*, the newsletter of the IUCN/SSC Task Force on Declining Amphibians, provides for communication among researchers working on this conservation problem. The newsletter contains information on recently funded research projects, abstracts from recent meetings, citations for recent reports and published papers, and advertises job opportunities. For further information contact: *Dr. James L. Vial, Task Force Coordinator, Center for Analysis of Environmental Change, EPA Environmental Research Laboratory, 200 SW 35th Street, Corvallis, Oregon 97333, USA; tel. (503) 754-4798.*

LETTER TO THE EDITOR

Dear Editor:

I found Mr. Rundquist's recent review (HR 24:75-76) of *Snakes of the United States and Canada: Keeping Them Healthy in Captivity, Vol. I*, to be quite unfair, taking numerous quotes out of context, and insinuating that I had actually suggested releasing exotic reptiles into native populations. In fact, if I may quote that section directly, the following words end the chapter on releasing: "One should never release exotics, mutants, or sick individuals. They may be very harmful to native populations."

Furthermore, I do not seek to "encourage the deliberate release of captives into wild populations . . . for the purpose of augmenting those populations." For goodness sakes, this chapter was meant to encourage ten-year olds to release their captive garter snakes and babies when they grew tired of them! It provides them with a technique for conditioning these snakes for release and a logical place to release them—no more. In addition, the text of this section clearly states that "no one knows how well snakes that have been raised (or even just maintained for a short while) in captivity adjust to living in the wild again." Also, it is clearly stated in this section that observing other members of the same species in an area "indicates that the habitat is suitable for that species although it doesn't tell you if that area can support more snakes of that species (that area may have already reached its carrying capacity, the maximum number of snakes it can support)."

In addition, this section was written nearly five years ago, a long time before we were aware of the deadly infectious nature of URDS in tortoises. Indeed, this was Mr. Rundquist's only valid argument against release, since the "genetic effect" he is so concerned about was addressed in the book by the statement: "Perhaps the safest and

Catalogue of American Amphibians and Reptiles

The *Catalogue of American Amphibians and Reptiles* is seeking qualified contributors. Many American and a number of U.S. taxa remain to be assigned (see the partial listing below).

To encourage contributions by students and herpetologists in developing nations, the Society for the Study of Amphibians and Reptiles is making the following offer: for each published account (assignment is subject to approval by the pertinent section editor—names are listed below—and the *Catalogue's* editorial board) the author will receive 100 consecutively-numbered previously-published accounts. Here is an opportunity to make a contribution to the herpetological community and simultaneously build a complete set of accounts (otherwise available for $215 from the Publications Secretary). For more information about this offer contact Robert Powell, CAAR Editor, Department of Natural Sciences, Avila College, 11901 Wornall Road, Kansas City, Missouri 64145, USA.

If you are interested in writing an account, please contact the pertinent section editor: **Marvalee H. Wake** (Gymnophiona), Department of Integrative Biology, University of California, Berkeley, California 94720, USA; **R. Wayne Van Devender** (Caudata), Department of Biology, Appalachian State University, Boone, North Carolina 28608, USA; **John D. Lynch** (Anura), School of Life Sciences, University of Nebraska, Lincoln, Nebraska 68508, USA; **Michael W. Klemens** (Testudines), American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024-5192, USA; **Andrew H. Price** (Sauria and Amphisbaenia), Texas Parks and Wildlife Department, 4200 Smith School Road, Austin, Texas 78744, USA; **Larry David Wilson** (Serpentes), Department of Biology, Miami-Dade Community College, Kendall Campus, 11011 S.W. 104th Street, Miami, Florida 33176, USA; **I. Sauria: *Callisaurus draconoides, Cnemidophorus flagellicaudus, C. gularis, C. inornatus, C. septemvittatus, C. sonorae, C. tigris, C. velox, Eumeces anthracinus, E. fasciatus, Gerrhonotus liocephalus, Holbrookia maculata, Phrynosoma modestum, Sceloporus jarrovii, S. scalaris, S. serrifer, Urosaurus microscutatus, Uta stansburiana.*

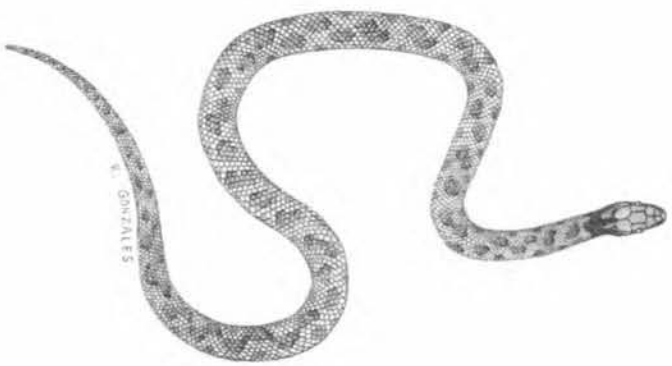
Serpentes: *Carphophis amoenus, Chilomeniscus cinctus, Chionactis, C. occipitalis, C. palarostris, Coniophanes, C. imperialis, Contia tenuis, Crotalus ruber, C. viridis, C. willardi, Diadophis punctatus, Elaphe guttata, E. obsoleta, Heterodon nasicus, Hypsiglena torquata, Lampropeltis getula, Leptodeira, L. septentrionalis, Masticophis bilineatus, Micrurus, Nerodia cyclopion, N. fasciata, Opheodrys aestivus, O. vernalis, Oxybelis, Regina alleni, R. rigida, Rhadinaea, R. flavilata, Salvadora, S. grahamiae, S. hexalepis, Sistrurus, Sonora, Storeria occipitomaculata, Tantilla gracilis, T. rubra, Thamnophis marcianus, T. radix.*

most logical place to release baby snakes is where their parents were captured." Indeed, radio-transmitter studies to date indicate that a corn snake may travel as much as 17 km in a straight line in one season, and that pine snakes have huge home ranges (Dick Franz, pers. comm.).



With regard to his comments on my views about the indigo snake, I must express amazement. He commented "as if captive breeding would have solved the problem of habitat destruction for this species." No, Mr. Rundquist, I do not think that captive breeding will solve the problem of habitat destruction, but it appears that little else will either. I am a firm believer in habitat preservation as a first line means of defense against extinction. I am a member of the The Nature Conservancy and even suggested that the readers of this book contribute to that cause and why. I noticed you carefully left this out of your quotations from the book.

I am also a realist. I live in Florida, where indigo snakes are supposed to be "protected." Indigo snakes have a home range of 75–400 hectares. Even in an area zoned for rural use, this translates into few long term viable populations over much of the state. This state is adding 400,000 new people per year, and even the gopher tortoise, which should be listed as endangered, will not be because of the tremendously negative economic impact that this will have. I would suggest that those who do not recognize the inevitable results of this kind of development are "incredibly naive," not those who suggest that captive breeding is a major positive force for the conservation of these animals. Even where human development is far away, such as in the national parks, pollution may be destroying entire populations of amphibians in the next few years. Can reptiles be far behind?

Lastly, if captive breeding and release are as inherently useless as Mr. Rundquist implies in his review, then why does the U.S. Department of the Interior suggest both of these alternatives be utilized in the species survival programs of the New Mexico ridgenose rattlesnake and the Concho water snake? Ask the respective state commissions of Florida and California how they would manage Florida panthers and California condors if they could do it all over again.

Mr. Rundquist has allowed our philosophical differences on the future of the remaining wilderness dictate his final non-recommendation of the book, in spite of his positive early comments about the "unique insights" with which he credits this book. If our debate here spawns a heated discussion among herpetologists about the role of herpetoculture in conserving elements of disappearing ecosystems, so be it.

ARTICLES

Preliminary Analysis Of Peripheral Blood Components Of *Macroclemys temmincki*

Peripheral blood components of approximately 60 species of reptiles including members of Testudines, Crocodylia, Sauria, and Serpentes have been published (Frye 1973; Girons 1970; Glassman et al. 1981). This project was undertaken to describe heretofore unstudied selected formed elements in the peripheral blood of *Macroclemys temmincki*.

Values for hemoglobin, hematocrit, red blood cell (RBC) counts and indices, and white blood cell (WBC) total and differential cell counts were determined from 10 alligator snapping turtles (2.8–31.8 Kg). The turtles were trapped from bayous and rivers in northern Louisiana, and transported after capture to the Northeast Louisiana University Turtle Research Facility and maintained in 1.5 x 1.5 x 1.5 m tanks at approximately 25°C during the study period (spring, 1991).

One to three mls of blood were collected in 3 ml heparinized (Lithium heparin) tubes via tail caudal vein puncture (Galbraith 1991; Powell and Knesel 1992). Thin smears of peripheral blood cells were stained with Wright stain (Wintrobe 1981) and examined to determine the percentages of cell types in the circulating blood. RBC's and WBC's were counted with a Neubauer hemocytometer, hemoglobins were determined by a cyanmethemoglobin colorimetric procedure (Sigma Diagnostics, P. O. Box 14508, St. Louis, Missouri, 63178, USA) and packed cell volumes were recorded from spun hematocrit tubes. Using determined hematocrit, hemoglobin, and the total number of red blood cells, mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH), and mean corpuscular hemoglobin concentration (MCHC) values were calculated.

The red blood cells were nucleated oval cells with homogeneous, translucent, pale pink cytoplasm. The oval, centrally located, dense nucleus contained a prominent chromatin condensation. Many of the cells were noted to contain intracorpuscular parasites, possibly *Haemogregarina* (Alleman and Jacobson 1992), *Haemoproteus*, or *Plasmodium* (Girons 1970) which have been reported to parasitize the RBC's of chelonians.

Cells in the lymphocyte series were composed of light blue cytoplasm and rounded ovoid nuclei with a coarse chromatin condensation pattern. The cytoplasm of some of the larger lymphocytes contained azurophilic granules (Girons 1970). Monocytes contained abundant blue-gray cytoplasm with a round, kidney shaped or lobulated nucleus (Frye 1973).

There were four types of cells in the granulocytic series: non-acidophils (similar in appearance to mammalian neutrophils), eosinophils, heterophils, and basophils (Alleman and Jacobson 1992; Frye 1973; Girons 1970). The non-acidophil (neutrophil) was seen as a large mononuclear cell containing abundant pale-pink to rose-violet granules in the cytoplasm. The small non-segmented nucleus, containing coarse clumped chromatin was usually located at the periphery of the cell. Heterophils and eosinophils were the most common white blood cells seen. The small dense dark blue nucleus, of each cell type, was eccentrically situated in the large cell and the cytoplasm was completely filled with eosinophilic granules. Heterophils differed from eosinophils by the presence of rod-shaped granules as opposed to the rounded granules of the eosinophil cell (Girons 1970). The circular cell of the basophil was easy to recognize by abundant dark-stained granules which filled the cell and obscured the nucleus.

Thrombocytes were noted as elliptical cells, occasionally seen in clumps, about one third the size of the RBC. Their spherical, highly chromophilic nucleus was centered in the blue gray cytoplasm. The nuclear:cytoplasm ratio was high with scant cytoplasm bordering

the nucleus. The thrombocytes were fragile and sometimes only the nuclei were present on the smear.

The number of WBC's per cubic millimeter of blood averaged 1,735. Per 100 cells, the average differential counts were eosinophils = 26.40, heterophils = 25.90, basophils = 19.70, nonacidophils (neutrophils) = 15.00, and monocytes = 3.30. The mean value for lymphocytes equaled 14.80.

Average hemoglobin (6.56 g/dl), hematocrits (22.8%), and RBC (419,000) values were used to calculate RBC indices: MCV, MCH, and MCHC = 551.50, 154.90, and 28.80, respectively. A summary of hematologic values of *Macroclemys temmincki* is presented in Table 1.

TABLE 1. Hematologic data for *Macroclemys temmincki*.

Parameter	Mean	Std. Dev.
	N = 10	
White Blood Cells (x 103/mm^3)	1.74	0.62
Eosinophils (per 100 cells)	26.40	4.81
Heterophils (per l00 cells)	25.90	4.95
Basophils (per l00 cells)	19.70	15.11
Non-acidophils (per 100 cells)	15.00	3.49
Lymphocytes (per 100 cells)	14.80	8.13
Monocytes (per 100 cells)	3.30	3.00
Red Blood Cells (x 105/mm^3)	419.00	56.82
Hemoglobin (g/dl)	6.56	0.77
Hematocrit (%)	22.80	4.23
Mean Corpuscular Volume (fL)	551.50	98.55
Mean Corpuscular Hemoglobin (pg)	154.90	25.99
Mean Corpuscular Hemoglobin Concentration (g/dL)	28.80	3.06

Hematological values found were comparable to previous data reported from other chelonian species (Melby 1974; Wintrobe 1981) with the exception of increased mean corpuscular volume and mean corpuscular hemoglobin. Further research is needed to describe the cytochemical staining characteristics of bone marrow and peripheral blood cells, and the identification of the intracorpuscular parasite.

Acknowledgments.—We would like to thank Jerry Liles and the medical technologists at North Monroe Hospital for their assistance.

Vertebrate Predation On The Neotropical Amphisbaenian *Leposternon wuchereri*

Predation on neotropical amphisbaenians is poorly documented (Greene 1988), and even more so for the specialized genus *Leposternon* (Gans 1971a). Here we report on instances of predation on *Leposternon wuchereri* by seven species of vertebrates (four birds, two snakes, and one mammal). *Leposternon wuchereri* is a slender species and reaches 460 mm SVL, and until this study it was poorly represented in collections (Gans 1971a; U. Caramaschi, pers. comm.).

Fieldwork was done in the vicinity of Mucuri, southern Bahia, Brazil (ca. 18°05'S, 39°36'W, 10 m). The area is covered by cacao groves, remnants of coastal rain forest, and pasture (see Carvalho-Filho and Silva 1976 for further description of the site). In July 1991 (dry season) and January 1992 (rainy season), we collected 72 specimens unearthed by clearing and plowing tractors. Vouchers of *L. wuchereri* found in gut contents of some predators are in the Museu de Historia Natural, Universidade Estadual de Campinas (ZUEC) and the Departamento de Biologia, Universidade Federal do Espirito Santo (ZUFES).

Leposternon wuchereri was found both during dry and rainy seasons at 20-40 cm depth in the upper layer of 40-100 cm deep sandy soil limited by a deeper clay layer. Our 72 specimens plus 10-12 individuals caught by birds within the same period were found in an area of about 3500 m^2, which would indicate a population density of about one individual/50 m^2. Major items in the diet were earthworms (ca. 80%), which suggests that *L. wuchereri* is a food specialist (Zamprogno et al. 1992).

We observed two turkey vultures (*Cathartes aura*) as they glided closely behind a tractor, scanning the ground. Upon spotting an exposed *L. wuchereri* one bird alighted and swallowed the prey while standing on the ground. One focal bird (cf. Altmann 1974) caught six *L. wuchereri* in ca. 50 min of such hunting. A crested caracara (*Polyborus plancus*), two yellow-headed caracara (*Milvago chimachima*), and an unidentified hawk (probably an immature *Buteo*) used another tactic. They perched along the path of the tractor and scanned the ground; when a *L. wuchereri* was unearthed, a bird alighted near the prey and also swallowed it on the spot. Our presence did not disturb the birds; indeed, we had to compete with them to secure *L. wuchereri* specimens.

One coral snake (*Micrurus corallinus*), which was also unearthed by the tractor, disgorged a *L. wuchereri* which it had swallowed tailfirst—an indication that the prey probably was caught underground (O.A.V. Marques, pers. comm.). One individual of the fossorial colubrid snake *Elapomorphus wuchereri* also had remains of *L. wuchereri* in its gut.

One juvenile crab-eating fox (*Cerdocyon thous*) was found dead along a road. Three whole *L. wuchereri* and pieces of three other individuals (including heads and tails) were found in its gut.

In general, the raptors and the fox we observed are opportunistic predators on healthy or wounded small vertebrates and with the exception of *Buteo*, all are known to scavenge (Nowak and Paradiso 1983; Sick 1985; pers. obs.). Although raptors or foxes would not habitually feed on *L. wuchereri* were it not for tractors, clearing and plowing are far from being unusual conditions in

eastern Brazil, and may be regarded as a mortality factor for subterranean reptiles such as *L. wuchereri*. The sight of crested caracaras following plowing tractors and picking up unearthed reptiles and other animals is a common one in Brazil (Sazima and Abe 1991).

Heavy tropical rains and floods cause amphisbaenians and subterranean snakes to surface (pers. obs.), making them vulnerable to predation. This may be the case of a *Mesobaena huebneri* found in the gut of a wader, *Belonopterus cayennensis* (=*Vanellus chilensis*) in Colombia (Gans 1971b).

The only known specialized predators on *Leposternon* seem to be the similarly fossorial coral snakes (*Micrurus*). Boulenger (1885) reported on a *M. "lemniscatus"* (probably *M. ibiboboca*, see Campbell and Lamar 1989), which had eaten a *L. polystegum*. *Leposternon microcephalum* is the predominant prey in the diet of *M. corallinus* at several localities in the coastal rain forest of southeastern Brazil (O.A.V Marques and I. Sazima, unpubl. data). Some species of the fossorial snakes of the genus *Elapomorphus* also seem to specialize on amphisbaenian prey (T. Lema, pers. comm.; pers. obs.) but data are too limited to elaborate further.

The coral snake *Micrurus laticollaris* was found to prey on the amphisbaenian *Bipes canaliculatus* (Papenfuss 1982). Autotomized tails were found in 3-17% of 3820 specimens of three species of Bipes, and the tail loss was attributed to predation (Papenfuss 1982). Only two out of the 72 specimens of *L. wuchereri* (ca. 3%) had scars on the tail, which is short and does not autotomize. This small percentage of tail-scarred *L. wuchereri* (presumably survivors of predation attempts) may be viewed either as slight predator pressure (see Papenfuss 1982, for such a view on *B. biporus*) or, more likely, as evidence of low predation survival rates in an amphisbaenian with limited defenses.

Some amphisbaenians invoke obvious antipredator behaviors such as biting and thrashing (*Amphisbaena alba*, Gorzula et al. 1977), or displays of an easily broken tail (*A. fuliginosa*, Greene 1973; *A. mertensii*, and *A. vermicularis*, pers. obs.). *Leposternon wuchereri* appears to have a limited antipredator repertoire which includes simple escape movements and production of a foul odor. These behaviors are ineffective against both visually-oriented (birds) and olfactorily-oriented (mammals, snakes) predators.

Acknowledgments.—A. S. Abe and J. P. Pombal-Jr. commented on our first drafts, J. R. Mendelson III criticized and greatly improved the final draft; J. L. Gasparini and M. G. Zamprogno helped in the field and laboratory; E. J. M. and M. J .L. Gazzinelli offered logistical support; U. Caramaschi and M. Porto confirmed our identification of *L. wuchereri*; the CNPq partly supported our studies. We dedicate this note to C. Gans.

Why Do Snakes Sleep On The Vegetation In Central Amazonia?

Snakes are prey for diverse predators, from invertebrates to mammals (see review in Greene 1988). However, many studies of vertebrate predation fail to consider carnivorous invertebrates (McCormick and Polis 1982). For instance, snakes may be preyed upon by scorpions, spiders, giant waterbugs, ants, and centipedes although literature references are rare (Greene 1988; McCormick and Polis 1982). In an extensive review of snake predators, Greene (1988) provided references for nearly 160 snake species, yet only 12 were by invertebrates.

Many diurnal snakes, even exclusively terrestrial species, are found at night sleeping on leaves and branches of low vegetation in Amazonian forests (Dixon and Soini 1986; Duellman 1978; pers. observ.). By sleeping above the ground, these snakes are less vulnerable to terrestrial predators. During a study on forest snakes in Central Amazonia, I found evidence that predation by ants may be a risk factor in sleeping on the ground for some snakes, here illustrated by the vine snake, *Oxybelis argenteus*, an arboreal colubrid.

Observations were made from July 1991 to October 1992 in a primary forest reserve (Reserva Florestal Adolpho Ducke, Instituto Nacional de Pesquisas da Amazonia) 25 km north of Manaus, Amazonas, Brasil. About 90 man-hrs of exclusive snake searching were conducted each month, during different times of the day. Visual searches were conducted by walking slowly along forest trails; the search effort extended to all visually-accessible microhabitats. Additional snake sightings were made during other activities. Each captured snake was measured (snout-vent length and tail length), weighed, marked by ventral scale clipping, and released at the site of capture.

A total of 356 individual snakes of 41 species were found (45 by day, 311 at night). Three species of diurnal, terrestrial snakes were found coiled asleep on the vegetation at night: four *Drymoluber dichrous* (0.7-1.6 m above ground), nine *Liophis reginae* (0.3-2.3 m), and three *Liophis typhlus* (0.3-0.7 m). Several arboreal or semiarboreal, diurnal and nocturnal snakes were also found coiled asleep or resting on the vegetation at night (e.g., diurnal species: *Chironius* spp., *Oxybelis* spp., and *Pseustes* spp.; nocturnal species: *Dipsas catesbyi*, *Leptodeira annulata*, and *Tripanurgos compressus*). No snake was found sleeping on the ground during this study.

Evidence of the risk of sleeping on the ground was observed in *Oxybelis argenteus*. Eighty-seven sightings were made. During the day, snakes (N = 10) were found active on low vegetation, searching for small frogs on the forest floor. At night (N = 77) they were found coiled asleep on thin branches of shrubs and small trees and on horizontal palm leaves, 8-400 cm ($\bar{x}$ = 138.3, SD = 69.5) from the ground. All snakes found at night were at least 30 cm above ground, except one found 8 December 1991, that was only 8 cm above ground. This snake had approximately 200 mm of its tail resting on the leaf litter of the forest floor. This part of the tail showed several small bites clearly made by ants, probably a species of *Camponotus*. The proximal portion of the bitten tail had deep bites that went through the vertebrae. The snake had no apparent prey in the gut and behaved normally when manipulated, except that it could not move the bitten portion of the tail. On 14 January 1992 I again observed this marked individual on a shrub, 120 cm from the ground and 23 m from the site of the first observation. By then it had lost the bitten part of the tail and three vertebrae were exposed at the tail tip, with no evidence of regeneration. This individual was not seen again. (At a site 250 km north of Manaus, I observed bites similar to those described above made by *Camponotus* ants on the tail and body of several snakes that fell on pitfall traps raided by these ants).

At the study site, other terrestrial, diurnal animals were found on low vegetation at night (e.g., insects, spiders, frogs, and lizards). Strong predation pressure may have forced snakes and other animals to avoid sleeping on the ground. Although many terrestrial vertebrates that prey on snakes occur in Neotropical forests (e.g., Cunha and Nascimento 1978; Dixon and Soini 1986; Duellman 1978; Janzen 1983), invertebrate predators, including carnivorous ants and tarantulas, also may have contributed to this pressure (see McCormick and Polis 1982). Tarantulas (Theraphosinae) are able to eat small to medium-sized snakes in captivity (pers. obs.); these spiders and carnivorous ants both are very common throughout Amazonia. As proposed by McCormick and Polis (1982), group foraging by ants and the large size of tarantulas may facilitate predation on relatively large vertebrates.

Acknowledgments.—Valuable assistence in fieldwork was provided by W. Oda, S. Egler, M. E. Oliveira, and J. B. Rocha; I. Sazima, M. E. Oliveira and P. Buhrnheim made helpful suggestions on earlier drafts of the manuscript; Instituto Nacional de Pesquisas da Amazônia allowed my work at Reserva Ducke; CNPq provided a providential grant. This study is a contribution of the Convenio Universidade do Amazonas/Instituto de Medicina Tropical de Manaus.

Aerial Basking By Hatchling Freshwater Turtles

Many freshwater turtle species exhibit aerial basking behavior (Boyer 1965). Janzen et al. (1992) described three observations of basking by hatchling freshwater turtles (considered, as in the present study, to include turtles in their first full growing season) for the species *Chrysemys picta*, *Kinosternon odoratum*, and *Trachemys scripta*. They commented on the lack of reports of basking behavior in hatchlings, and were able to cite similar observations for only six other species (Table 1). They suggested that hatchling basking is more common than can be inferred from literature records, either due to researchers' inability to observe the phenomenon or their failure to report it.

[1]References attributed to Vogt are observations confirmed by hand capture while snorkeling (R. Vogt, pers. comm.).
[2]Cited as pers. comm. from D. Moll and E. Moll.

I report basking behavior for hatchlings of six species for which it has not been previously reported, as well as five for which it has, and include unpublished observations of hatchling basking (R. Vogt, pers. comm.) (Table 1). These observations suggest that basking by hatchling turtles is indeed common, and basking by hatchlings is shown to occur both among larger conspecifics, and segregated by basking substrate (with hatchlings often using smaller branches or logs) and occasionally by habitat.

Methods.—Observations were made either through capture techniques that rely on the basking habit of turtles (dipnetting and hand capture of basking turtles and basking traps), or with a 36X spotting scope. Captured hard-shelled turtles can be readily identified as hatchlings by inspection of growth rings (only a "zero" ring is present in hatchlings). Positive identification of turtles as hatchlings when viewed with a spotting scope is more problematic, but is facilitated by the fact that rate of growth declines progressively with age in turtles (e.g., Dunham and Gibbons 1990), such that hatchlings exhibit a marked difference in body size from other cohorts in a population. I have found that it is best to assess the size of a turtle by viewing it with the naked eye after observing it through a spotting scope, or by scaling it against larger conspecifics with which it may be basking. Additional useful diagnostic characteristics of hatchlings are that their heads are larger relative to body size, and their shells are rounder in a horizontal plane, than in older turtles. It is possible that some of the spotting scope observations reported herein as involving hatchlings actually involve turtles that were in their second growing season, particularly for individuals that had grown relatively slowly in their first season. I am confident, however, that most or the vast majority of these turtles were hatchlings.

Data were collected during a mark-recapture census of a northern Idaho population of *Chrysemys picta* in 1986 and 1987 (the Syringa Trailer Court population in Lindeman 1990). Principal means of capture were dipnetting turtles as they basked along the shorelines of three adjacent ponds, and basking traps. In 1992 I began population surveys of various turtle species in Kentucky Lake, an impoundment of the lower Tennessee River in Kentucky. Basking-dependent capture methods used included hand capture and basking traps.

A spotting scope survey of basking turtles was conducted between 24 July and 8 August 1992 in several major rivers of Mississippi, Louisiana, Texas, and Arkansas. Drainages surveyed included the Tombigbee, Pascagoula, and Pearl in Mississippi, the Sabine in Louisiana and Texas, the Trinity, Brazos, Colorado, and Guadalupe in Texas, and the Red in Arkansas. At each site (defined as an access point on the river, usually at a road crossing), a single count of basking turtles present was made from shore.

TABLE 2. Captures of basking *Chrysemys picta* hatchlings in an Idaho population. I = Individuals (excluding recaptures), I+R = Individuals + recaptures. No hatchlings were recaptured in either year.

Year	Capture method	Number of hatchlings	Total numbers captured I	Total numbers captured I+R	Percent hatchling I	Percent hatchling I+R
1986	Dipnet	5	97	139	5	4
	Basking trap	0	17	18	0	0
	Combined	5	109*	157	5	3
1987	Dipnet	9	128	203	7	4
	Basking trap	4	121	171	3	2
	Combined	13	177*	374	7	3

*Combined numbers are not additive because some individuals were caught by both methods.

I made four long-term observations of basking behavior of Kentucky Lake turtles using a spotting scope in 1992, from partial concealment afforded by shoreline vegetation. Absolute numbers of each species could not be determined due to the tendency for turtles to submerge and then re-emerge over the course of observation. Instead, minimum numbers of each species were determined based on maximum numbers seen simultaneously, together with notes on different size classes and occasional distinctive individual markings.

TABLE 3. Hatchling turtles observed basking during a survey of Gulf Coast river drainages, 24 July – 8 August 1992.

Species	Number of hatchlings (Number of different sites)	Number of non-hatchlings at same sites	Total number of individuals seen (Total number of sites where seen)	Percent hatchling: Sites with hatchlings	Percent hatchling: All sites
Apalone spinifera	1 (1)	0	3 (3)	100	33
Graptemys caglei	0	—	3 (2)	—	0
G. flavimaculata	0	—	9 (3)	—	0
G. nigrinoda	1 (1)	6	10 (3)	14	10
G. oculifera	2 (1)	15	27 (2)	12	7
G. ouachitensis ouachitensis	0	—	13 (3)	—	0
G. ouachitensis sabinensis	2 (1)	40	56 (3)	5	4
G. pseudogeographica	0	—	13 (6)	—	0
G. pulchra	6 (3)	9	22 (7)	40	27
G. versa	2 (1)	6	16 (3)	25	13
Kinosternon carinatum	0	—	6 (3)	—	0
Pseudemys concinna	1 (1)	1	15 (5)	50	7
P. texana	0	—	45 (10)	—	0
Trachemys scripta	0	—	14 (7)	—	0
Totals	15 (8)	77	252 (33)	16	6

Results.—Hatchlings comprised 5% and 7% of the *C. picta* captured by one or both capture methods in 1986 and 1987, respectively (Table 2). Counting recaptures, hatchlings constituted 3% of all captures in both years (Table 2). At Kentucky Lake in 1992 I captured seven aerially basking hatchlings by hand: five *Trachemys scripta* (plus one recapture), one *Graptemys ouachitensis*, and one *Apalone mutica*. The latter, which as a trionychid exhibited no growth rings, had a prominent yolk sac scar and was 38 mm plastron length and 53 mm carapace length on 18 June (compare to hatchling body sizes reported in Table 4 of Plummer 1977). One additional hatchling *G. ouachitensis* drowned when it became entangled in netting inside a basking trap.

Table 3 details numbers of hatchling turtles observed during the 1992 survey of Gulf Coast drainages. Fifteen of 252 turtles (6%) identified during this survey, of 7 of the 14 species seen, were judged to be hatchlings (Table 3). Negative results generally were obtained for species seen in lesser abundance (Table 3).

Two longer observations were made on 13 and 20 June 1992 in Kentucky Lake, both involving single large logs, near the creek inlets of Jones Creek Embayment and Nickell Cove, respectively. Minimum numbers of turtles seen were 17 *Trachemys scripta*, 4 *Pseudemys concinna*, and 1 *Graptemys ouachitensis* for the first observation, and 9 *T. scripta*, 3 *G. pseudogeographica*, 2 *P. concinna*, and 1 *G. ouachitensis* for the second. None of these were hatchlings; however, during the second observation a hatchling *T. scripta* basked nearby for approximately two hours on a small branch that protruded ca. 15 cm above the water.

On 19 August 1992, I observed basking turtles from 0852 until 1430 h in a cove on the canal that connects Kentucky Lake to Lake Barkley, an impoundment of the lower Cumberland River. I observed a minimum of 16 *Graptemys ouachitensis*, 13 *Trachemys scripta*, 3 *G. pseudogeographica*, and 3 *Pseudemys concinna* (Table 4). Of these, at least five hatchling *T. scripta* and two hatchling *P. concinna* were present. Basking times for the *T. scripta* hatchlings were as follows: on a small branch in shallow water, 0852-1018 h and 1040-1223 h (probably the same individual); on a large log in shallow water, 0907-1115 h and 1008-1115 h; and on a floating log in deeper water, 0940-0945 h, 1010-1257 h, and 1345-1400 h (possibly a single individual), and 1045-1100 h. Basking times for *P. concinna* hatchlings were 0852-1018 h and 1052-1227 h on the first site (probably the same individual) and 0915-1130 h on the second site. The percent of turtles that were hatchlings declined throughout the observation, particularly after 1100 h; however, this may have been due to the later peak of basking *Graptemys*, of which none were hatchlings, since peak numbers of hatchlings and of all individuals of *T. scripta* and *P. concinna* coincided at 1100 h Table 4).

Finally, on 31 August 1992, basking *Apalone mutica* were observed on a gravel bar in Nickell Cove, from 0910 until 1230 h. Maximum density was seven, of which one was judged to be a hatchling. It basked from 1108 until 1137 h.

Discussion.—Including the unpublished observations of R. Vogt (pers. comm.; see Table 1), aerial basking for hatchling freshwater turtles has now been described for 20 species in four families (Table 1), and is very likely characteristic of other species in which larger individuals bask habitually. The apparent ease with which hatchlings are observed basking confirms speculation by Janzen et al. (1992) that this is a common behavior that has merely been little noted in literature accounts of basking behavior. Many of the hatchlings observed basking in the present study were among larger con- and heterospecifics, although some used smaller basking substrates that might not have held larger turtles, and some observations suggest habitat segregation on a larger scale as well. For instance, many of the Idaho *Chrysemys picta* hatchlings were dipnetted from atop emergent shoreline grasses or *Typha* leaves in an area of one pond not frequented by larger turtles. Three of the hatchling *Trachemys scripta* captured at Kentucky Lake were in a shallow cove of approximately 40 m^2 adjacent to a boat ramp, where I have frequently observed hatchlings and small juveniles, but never adults, of *T. scripta*, *Graptemys ouachitensis*, and *G. pseudogeographica*. Most hatchlings seen during the survey of Gulf Coast river drainages were observed among larger conspecifics (Table 3). Exceptions included two *G. pulchra* hatchlings seen in the Chickasawhay River near Meehan Junction, Mississippi, and the two *G. versa* in the Llano River near Junction, Texas, which basked in separate backwaters apart from six larger *G. versa* seen in the main channel. Near Shubuta, Mississippi, the only turtles seen were a hatchling *Apalone spinifera* and a hatchling *Pseudemys concinna* which shared a small (1 m long) log with a larger *P. concinna*. Finally, the small branches in shallow water utilized by two hatchlings in the observation conducted 19 August 1992 at Kentucky Lake were also utilized by up to three juvenile *T. scripta* and one juvenile *G. ouachitensis*, but no adult turtles.

TABLE 4. Observations of basking turtles in a cove on the canal connecting Kentucky Lake and Lake Barkley, conducted 19 August 1992. Numbers of hatchlings appear in parentheses.

Time	*Trachemys scripta*	*Pseudemys concinna*	*Graptemys ouachitensis*	*Graptemys pseudogeographica*	Total	Percent hatchling
0852	1(1)	1(1)	—	—	2(2)	100
0900	3(2)	2(1)	1	—	6(3)	50
0915	3(2)	3(2)	2	—	8(4)	50
0930	4(2)	3(2)	3	—	10(4)	40
0945	4(3)	2(2)	2	—	8(5)	63
1000	4(4)	3(2)	4	—	11(6)	55

1415	3	—	7	—	10(0)	0
1430	3	—	7	—	10(0)	0

Boyer (1965) discussed observations of basking behavior in terms of coincident physical conditions. He concluded that basking is primarily, but not exclusively, a thermoregulatory behavior. Turtles bask as a means of elevating their body temperature, presumably to facilitate subsequent activities such as foraging, mating, or nesting, and possibly also to increase digestive efficiency. Observations of turtles basking under natural conditions indicate that basking is used to maintain preferred body temperatures (Crawford et al. 1983; Schwarzkopf and Brooks 1985). Other benefits derived from basking apparently include drying of the epidermis, which eliminates plant and animal parasites and aids in ecdysis (Boyer 1965), and exposure of turtles to grackles (*Quiscalus quiscula*) which consume attached leeches (Vogt 1979). Pritchard and Greenhood (1968) speculated that basking may also promote vitamin D synthesis.

Presumably, the same thermoregulatory and other physiological demands that cause older turtles to bask are also applicable to hatchlings. That such demands are important is seen in the time spent basking, which cannot be spent foraging or engaging in reproductive activities (Crawford et al. 1983), and in the fact that basking exposes turtles to predation (e.g., Ross 1988). Under threat of predation, hatchlings appear to have the same escape behavior as larger turtles—diving into the water and swimming downward and away—as several hatchlings have used this strategy effectively in Kentucky Lake to avoid hand capture by me. Although their smaller size and less calcified shells expose them to a greater range of potential predators, my observations together with those of Janzen et al. (1992) and Vogt (pers. comm.) suggest that the cost-benefit ratio of basking still favors basking over not basking for hatchling turtles. Further studies should examine possible differences between hatchlings and larger turtles in time spent basking. Such differences, if they exist, may relate to differential heating relationships based on body size and shell shape (Boyer 1965), and ontogenetic differences in diet and metabolism (e.g., as related to calcium intake and shell formation; Clark and Gibbons 1969).

Acknowledgments.—I thank David Auth, Kurt Buhlmann, Fred Janzen, Cindy Rebar, and Dick Vogt for reviewing the manuscript, and Dick Vogt for graciously sharing his unpublished observations.

Shifts In Activity Patterns In Lizards

Lizards can generally be categorized according to their activity patterns: nocturnal, diurnal, crepuscular, or a combination thereof. However, sufficient examples exist to suggest that many species might exhibit activity outside of their normal (or recognized) activity periods. These exceptions appear, in part, to be driven by three major classes of events: effects of urbanization, species interactions, and resource availability.

Urbanization.—On 23 November 1990, between 1930 and 2000 h, two actively foraging *Cryptoblepharus poecilopleurus* (a diurnal skink) were collected under porch lights of a dwelling on Cocos Island, Territory of Guam. This species was also observed in 1988 feeding at night under lights on Cocos Island (G. Rodda, pers. comm.). We have observed *Anolis carolinensis* actively foraging in vegetation at 0530 h under lights at a house in Edinburg, Hidalgo Co., Texas on 16 October 1992. Schwartz and Henderson (1991) observed nocturnal foraging in normally diurnal *Anolis bimaculatus*, *A. cristellus*, and *A. sagrei*. Powell and Henderson (1992) reported three additional diurnal species (*A. marmoratus*, *A. sabanus*, and *A. gingivinus*) that foraged around lights nocturnally. Schwartz and Henderson have termed the above phenomena the "night-light" niche in which artificial lights extend the foraging period for typically diurnal lizards.

Species Interactions.—*Hemidactylus frenatus* has been introduced on islands throughout the tropical Pacific Basin and has had presumed negative impacts on native gekkonids (McCoid 1993; McKeown 1978; Zug 1991). Petren et al. (1993) have shown experimentally that *H. frenatus* replaced *Lepidodactylus lugubris* and concluded that avoidance behavior by *L. lugubris* was responsible for observed changes. In an unpublished study on Hawaii, Lazell (in litt.) documented the replacement of *L. lugubris* by *H. frenatus* but did not speculate if this replacement was due to behavioral interaction or direct predation. Our observations in the Territory of Guam indicate that predation probably plays a role in interactions between

these two species. We have observed adult *H. frenatus* pursuing and consuming juveniles and hatchlings of both conspecifics and *L. lugubris*. We have also repeatedly observed that small *H. frenatus* (19-30 mm SVL) became active about 1400 h in a house on Guam (McCoid and Hensley 1991) and openly foraged on ceilings and walls. At about dusk (1830 to 1930 h), these hatchlings and juveniles retreated to refugia and either reduced their foraging areas to immediately adjacent to the refugia or did not emerge until the following day. At dusk, adult and subadult (to 65 mm SVL) *H. frenatus* emerged from daytime refugia and foraged in the areas formerly occupied by much smaller *H. frenatus*. We suggest that this may be an heretofore unrecognized activity shift in young *H. frenatus* to reduce cannibalism.

Resource Availability.—McKeown (1978) mentioned that *Hemidactylus garnoti* may emerge diurnally to feed. Zug (1991) noted the same phenomenon for *Gehyra oceanica* and *G. vorax*. We have observed (during the span of daylight hours), on numerous occasions, three species of nocturnal gekkonids (*L. lugubris*, *G. oceanica*, and *Perochirus ateles*) feeding diurnally on Guam and Cocos Island (Territory of Guam). *Lepidodactylus lugubris* is a common human commensal that has been observed numerous times diurnally feeding on sugar-based food scraps. On Guam, we have also observed this species diurnally feeding on the blooms (and/or insects attracted to the blooms) of palm trees (*Cocos nucifera*). Groups of one to five have been seen around a single bloom. On Cocos Island, we have observed both *G. oceanica* and *P. ateles* diurnally feeding on palm blooms (and/or insects attracted to the blooms) in groups of one to five. Because these feeding events do not involve large numbers of lizards, we suspect that only the inhabitants of that tree are involved in the periodic feeding episode even though not all trees are in bloom at the same time. We have also observed that these feeding assemblages involve only conspecifics. We suggest that some normally nocturnal gekkonids in the tropical Pacific routinely alter activity patterns to take advantage of periodically available resources.

Acknowledgments.—Portions of this report were funded by the Endangered Species Conservation Program, Project E-4 (to Guam). Gordon Rodda kindly shared his observations and Skip Lazell unpublished data and literature.

SSAR Grants-in-Herpetology

Proposals are now being accepted for the 1994 SSAR Grants-in Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address educational projects, speakers' fees, regional research, defrayment of one-time-only costs, or other purposes that would strengthen regional societies. Proposals may be submitted by regional herpetological societies or by individual members and must be accompanied by a letter of support from the current president of the regional society.

2. HERPETOLOGICAL RESEARCH OR EDUCATION IN ZOOS. Proposals may address any herpetological endeavor conducted in zoos, such as improvement of displays, interpretive graphics, husbandry or behavioral research. A letter of support from the herpetological curator or the director of the sponsoring zoo must accompany the proposal.

3. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species. Proposals must be from individuals only and must be accompanied by a letter of support from another member of the SSAR.

4. FIELD WORK. Proposals may address support for travel to ecological study sites or for survey collections. Proposals normally submitted in the CONSERVATION or GRADUATE STUDENT RESEARCH categories should be submitted here if travel or field station support is sought. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

5. GRADUATE STUDENT RESEARCH IN HERPETOLOGY. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only. Applications must be accompanied by a letter of support from the student's major advisor or committee chairperson.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR with the exception of those applying in the REGIONAL HERPETOLOGICAL SOCIETY category. Applicants are limited to submission of one proposal in one category per year. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) BACKGROUND AND OBJECTIVES of the proposed project. (B) METHODS of carrying out the project. (C) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). (D) BRIEF RESUMÉ of the applicant or project coordinator. (E) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages excluding resume and budget.

Applicants must designate to which of the five categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than 31 DECEMBER 1993 to be considered. Failure to meet the guidelines may result in elimination of a proposal from consideration. The awards will be announced by 1 April 1994. Successful applicants will be expected to submit a written report of the results of this support within a reasonable amount of time after the project year is completed. They are also encouraged to submit the results of research projects for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Dale Belcher, Chair, SSAR Grants-in-Herpetology, Rio Grande Zoo, 903 Tenth St. SW, Albuquerque, New Mexico 87102-4098, USA. Tel. (505) 843-7413, FAX (505) 842-7281.*

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number and/or size of awards. Your tax-deductible contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

Field Herpetologists Needed

Six wildlife research assistant positions will be available from 1 March 1994 through 31 October 1994 to work on the herpetological and small mammal studies in the Ozark Forest Ecosystem Project. Successful applicants will participate in a study of the effects of even- and uneven-aged forest management on amphibians, reptiles, and small mammals in Ozark forests. Workers must be able to identify amphibians, reptiles, and small mammals to species. The hourly wage is $4.69/hr for a 40-hr work week. Housing, utilities, and vehicles are provided. To apply, submit an Application for Employment, résumé, cover letter, and a list of references to *Rochelle Renken, Missouri Department of Conservation, Wildlife Research Section, 1110 S. College Ave., Columbia, Missouri 65201, USA (tel. 314/882-9880).* Applications must be received by 5:00 p.m. Monday, 1 November 1993.

Natural Occurrence Of Shell Abnormalities In Hatchling Red-Footed Tortoises (*Geochelone carbonaria*)

The characteristic arrangement of the scutes covering the carapace and plastron of turtles is of wide use in the taxonomy of the order (Lovich and Ernst 1989; Lovich et al. 1991; Pritchard 1979). Abnormalities in the carapace and plastron scutes, however, are frequently reported for different species of turtles (Pritchard 1979; Zangerl 1969). Experimental studies have shown that such abnormalities can be related to inadequate temperature or humidity levels in which the embryo has developed (Lynn and Ullrich 1950; Packard et al. 1987). Nevertheless, the frequency of abnormalities in turtles, and even reptiles, in nature is poorly known.

A group of hatchling red-footed tortoises, *Geochelone carbonaria*, was confiscated from poachers by federal forest police during transportation to southeastern Brazil. The tortoises were caught in northeastern Brazil to be sold in the pet trade. Examination of the 163 hatchlings revealed that 19% had shell abnormalities on either the carapace or plastron. The presence of one or two supranumerary scutes was present in 9.2%. of the individuals, and was by far the most common abnormality. In 6.1% of tortoises, the carapace was deformed; 3.1% had the scute partially or completly fused, and 2.4% showed irregular arrangement of the scutes. The scutes most affected were vertebrals (37.9%), pleurals (31%), marginals (24%), and supracaudal (3.4%). Table 1 depicts the frequency of scute abnormalities observed in our sample.

Geochelone carbonaria has a wide geographic distribution throughout South America (Pritchard and Trebbau 1984). The female produces 2–7 eggs, measuring ca. 4.9 x 4.2 cm, each reproductive season (Medem et al. 1979; Pritchard and Trebbau 1984). The eggs are buried in a shallow hole at an approximate depth of 6–10 cm (Pritchard and Trebbau 1984). The incubation time ranges from 105 to 202 days (Medem et al. 1979). *G. carbonaria* is often found in temporary habitats (Pritchard and Trebbau 1984), such as the "caatinga," a thorn shrub vegetation found in most of northeastern Brazil, where the hatchling tortoises were obtained. In such an environment, with eggs buried in a shallow nest, and having long incubation periods, embryos are often exposed to harsh seasonal conditions. Under these circunstances it is reasonable to suppose that, as in other chelonian species so far reported (cf. Lynn and Ullrich 1950; Packard et al. 1987), environmental conditions during incubation may result in embryonic deformities in *G. carbonaria*.

TABLE 1. Frequency of carapace scute abnormalities in a sample of 163 hatchling *Geochelone carbonaria*. Abbreviations: vert. = vertebrals; pleur. = pleurals; marg. = marginals; s.c. = supra-caudals; nc = normal count for the species.

The abnormalities observed in hatchling *G. carbonaria* are similar to those reported for experimental studies in which the eggs of other species were exposed to temperature or humidity stress (Lynn and Ullrich 1950). The experimental results suggest that the abnormalities we observed may be caused by environmental stress during incubation. However, severe deformities like those reported by Lynn and Ullrich (1950) were not seen in our sample of *G. carbonaria*. However, Lynn and Ullrich (1950) dissected the eggs at the end of the incubation period, and removed embryos with gross deformities. If such severe deformities occurred in *G. carbonaria*, the young turtles may fail to emerge from the egg or the nest, or may be discarded by poachers. Therefore, the incidence of abnormalities in *G. carbonaria* may be even higher than here reported.

Shell abnormalities were observed in one fifth of the sample of hatchling *G. carbonaria* studied. However, scute abnormalities like those here reported are also frequently observed in adult tortoises (Pritchard 1979; pers. observ.). This finding may suggest that these scute abnormalities do not affect the fitness of the red-footed tortoise.

Acknowledgments.—We thank the Brazilian Environmental Institute (IBAMA) for the donation of confiscated tortoises. We are especially grateful to F. Bonatti and E. M. Tonetto for laboratory assistance. An earlier version of the manuscript was largely improved by the comments of Célio F. B. Haddad and A. P. Cuz Neto. ASA was supported by CNPq grant 301330/80-8.

POINT OF VIEW

Comments On The Distribution Of *Clemmys insculpta* On The Coastal Plain Of Maryland

"The problem with wood turtles is that people just can't leave them alone."—Lazell (1976)

Of the 46 species that comprise the reptile fauna of Maryland, the distribution of the wood turtle, *Clemmys insculpta*, is the most enigmatic and is one that unfortunately will never be accurately known. This situation arises from three factors: (1) the species is at one limit of its range in Maryland (Conant and Collins 1991; Ernst 1972; Iverson 1992) and distributions typically become erratic under such circumstances, (2) this active and handsome turtle has great appeal that frequently leads to its collection and release or escape elsewhere, and (3) there has been, and continues to be, inadequate documentation of distributional data published by Marylanders, not only for the wood turtle but for the herpetofauna generally. This review has been prompted by a recent article by Norden and Zyla (1989), who reported a number of wood turtle localities from the coastal plain of southern Maryland. I think these authors have not attended to the second and third points, and have not seen the necessity to be critical of their records, relying instead on sheer numbers to speak for themselves. Criticism of their note is thus hindered somewhat because the authors do not explicitly state what their records mean. Are they evidence of natural occurrence and supportive of a previously mapped distribution (Ernst 1972), or are they suggestive of introductions, which have a rich tradition in the area (Brady 1937; Carver 1970; Conant 1958a; Cooper 1959, 1960, 1961, 1965; Dukehart 1884; Fowler 1943, 1945; Groves, J. D. 1972; Groves, M. F. 1940; Hardy and Mansueti 1962; Harris 1966, 1968, 1969b, 1975; Mansueti 1941a, b; Mansueti and Wallace 1960; Manville 1968; McCauley 1945; Nemuras 1964; Nemuras and Sparhawk 1966; Norman 1939; Polley 1989; Rambo 1992; Reed 1956b, c, 1957, 1958a; Schwartz and Dutcher 1961; Truitt 1939)? Or are they perhaps a combination of the two? The first possibility seems to be what the authors believe, and it is on this assumption that the following comments are based.

The earliest record of the wood turtle on the coastal plain of Maryland appears to be USNM 14582 from Havre de Grace, Harford County, collected in 1886. Havre de Grace lies just below the Fall Line at the mouth of the Susquehanna River, and precisely where the specimen was taken is not known. Henshaw (1907) mentioned this specimen and McCauley (1945) cited and mapped it, but he did not take the locality literally and regarded *Clemmys insculpta* as absent from the coastal plain. In any event, the Susquehanna River Valley has undoubtedly been an important dispersal corridor for the wood turtle (the species is well documented upstream—Conant 1958a; Cooper 1949; McCoy 1982; Prince et al. 1955) and the record presents no distributional problem. As recorded by McCauley (1945), Surface (1908) was the first author to report *Clemmys insculpta* from an unquestionably coastal plain locality at White Marsh, Baltimore County. McCauley (1945) clearly discounted this record, but Reed (1956a) found it quite acceptable and suggested that McCauley was misguided and unclear in his reasons for not accepting it. Having examined the disputed passage in Surface (1908), I agree with McCauley that there is no basis for assigning this vague verbal report to *Clemmys insculpta*, and that Surface was reckless in so doing. It should also be noted that McCoy (1982) considered Surface's herpetological work to "consist largely of uncritical compilations from the literature." Norden and Zyla (1989) do not mention either of these localities.

The next report from the Maryland coastal plain, this time on the Eastern Shore, was that of Norman (1939), who noted a specimen (NHSM 529; discarded) found "near Easton City," Talbot County, taken on 9 September 1939. Conant (1958a) and catalogue data fix its point of collection more precisely at 4.5 miles (7.2 km) W Easton, AOR on Md. Route 17 (now Md. Route 33). Fifty years after the collection of this turtle, and without any additional material having been reported or taken anywhere near Easton, it is surprising to see Norden and Zyla (1989) giving credence to this record. Nearly all herpetologists (Conant 1958a, b, 1975; Conant and Collins 1991; Cooper 1960, 1965; Harris 1969b, 1975; McCauley 1945) who have worked comprehensively with the Maryland herpetofauna have rejected this locality, the lone exception being Reed (1956a, b, c, 1958b). Nonetheless Norden and Zyla have paid little heed to the weight of evidence against this record, and have chosen to cite Reed (1956a, 1958b) for support. Reed (1956a) was "sure" *Clemmys insculpta* occurred in the vicinity of Easton because "Many plants are known off the Piedmont Plateau only in this one Coastal [sic] region of the Eastern Shore." Leaving aside the above locality clarification, which places the site out on a narrow peninsula, it seems dubious justifying a 70 km (across the Chesapeake Bay from Bennings, District of Columbia) or 90 km (from Havre de Grace, Harford County) range extension of a vertebrate on the basis of "many" disjunct species of plants. More important, Reed, as well as Norden and Zyla, are under the misapprehension that the wood turtle is a piedmont species, not recognizing that it is a montane (in Maryland especially) and northern animal whose range encompasses very little of the piedmont, regardless of how liberally one accepts locality records. Thus there can be no convincing correlation between a montane turtle found in a remote area of the coastal plain that possesses an unquantified number of piedmont plants. Reed (1958b) listed localities for and crudely mapped 17 amphibian and reptile taxa that he considered to be "predominantly Piedmont in distribution in Maryland and the Delmarva Peninsula, but that are also known from the Coastal Plain of southern Maryland and the Delmarva Peninsula." This paper fails remarkably in its objective, with only one taxon, *Natrix* (=*Regina*) *septemvittata*, meeting the criterion. Six of the species listed, *Carphophis amoenus*, *Haldea* (=*Virginia*) *valeriae*, *Lampropeltis getulus*, *Opheodrys vernalis*, *Storeria occipitomaculata*—and *Clemmys insculpta*—are emphatically not "predominantly Piedmont in distribution." Reptile distributions in Maryland were well known long before Reed's 1958b article (McCauley 1945) and 45 years of subsequent field work have not significantly altered them. No comprehensive work on the amphibians of Maryland existed prior to Reed's efforts in herpetology (and none exists today), but had he consulted his own privately published specimen lists or, better, thoroughly surveyed museum holdings, he might not have committed so many egregious errors. If Norden and Zyla (1989) had wanted to build a case for the occurrence of *Clemmys insculpta* on the central Eastern Shore, they would have been better served by citing one of Norden's own notes (Lee and Norden 1976) and papers mentioned therein.

The article by Norden and Zyla (1989), the focus of this review, records 12 new localities for the wood turtle in southern Maryland: three in Anne Arundel County and nine in Prince George's County; the species had not been reported before from the former county. They also plot two previously mapped sites shown by Ernst (1972) in southern Maryland. Superficially this appears to be impressive evidence of natural occurrence, but I believe there are grounds for skepticism.

Although I find none of Norden and Zyla's localities compelling, I do find some more implausible than others. It is highly unlikely that naturally occurring populations of *Clemmys insculpta* could exist near Colmar Manor and at "Mt Rainer" (Mount Rainier) and remain undetected until 1989. The two localities, while only about 3.0 km apart, lie in a densely populated portion of Prince George's County and within 2.0 km of the District of Columbia, an even more heavily urbanized area. The National Museum has extensive holdings for the District of Columbia and surrounding counties that date

back over one century, yet no specimens of *Clemmys insculpta* from Prince George's County (or Anne Arundel County) are present in the collection. The nearest records to those under discussion lie in the District of Columbia (USNM 62556; verified) and, for Maryland, along the Potomac River in the piedmont of adjacent Montgomery County (USNM 36801, 77029, 86612, 107640-107641; all verified). Although a short distance from the Colmar Manor and Mount Rainier sites, these localities have age and numbers to commend them. All were collected between 1906 and 1938, and four of the five Montgomery County specimens were taken in the Cabin John–Plummer's Island area; the other is from a few km farther upstream at Great Falls. In addition to summarizing the Montgomery County and one of D.C. records, Clark (1930) provided additional support for the natural occurrence of wood turtles along the Potomac River in the piedmont of adjacent Virginia, citing several localities, with the oldest (USNM 61095) dating from 1918. The D.C. specimen, for which there are no further locality data in the USNM catalogue, is almost certainly the turtle reported by Shufeldt (1919) and stated to be from near Bennings. Palmer (1919) also mentioned three wood turtles from Eastern Branch (since renamed Anacostia River) without further specificity, but presumably from the District of Columbia. Although these D.C. records, all from the coastal plain and also overlooked by Norden and Zyla, could be viewed as providing support to the upstream localities of Colmar and Rainier, they predate them by 70 years and no reports or specimens have appeared in the interim. It should also be noted that the turtle found at the junction of "Washington Road and Tantallion Drive" (Fort Washington Road and Tantallon Drive) was found in the middle of a residential area, as were the two from Greenbelt. There has also been some confusion with the Fort Washington record and their "Piscatoway Creek Road" [Piscataway Road (Md. Route 223)] site. Both localities have been mapped at the latter spot, although they are at least as far apart as the Colmar Manor and Mount Rainier sites, which were plotted separately.

Like the Colmar Manor and Mount Rainier sites, no reliance can be placed on the Elvaton, Anne Arundel County record. Interest in the amphibians and reptiles of northern Anne Arundel County has been keen since the time of Mansueti (1941b), and was particularly pronounced during the 1960s and 1970s. This section of the state produced many members of the Maryland Herpetological Society, and gave rise to its predecessor and brief competitor, the Free State Herpetological Society. The area has been thoroughly explored, as a glance at Harris (1969b, 1975) will confirm, yet the wood turtle from Elvaton is the only one to surface. I searched the collector's (the late E. Clyde Prince) herpetological notes (present in the Department of Biology, Towson State University) and found no mention of this unusual find, perhaps because Prince himself did not consider the specimen significant.

One unwarranted action in the article by Norden and Zyla is the liberty they have taken with a paper by Ernst (1972). Norden and Zyla (1989) state: "The only other author to actually give Coastal Plain records for this species was Carl Ernst (1972), who published a map showing it [*Clemmys insculpta*] to be generally distributed west of the Fall Line but included two records for the Maryland Coastal Plain, one north-west of Annapolis and the other in eastern Charles County." Although Ernst did indeed publish a map showing at least two localities in southern Maryland, nowhere in his account does he provide any geographic details. Furthermore, Ernst's map is so small that it is impossible to state anything specific about the records he has plotted. This notwithstanding, Norden and Zyla confidently plot one of Ernst's sites in extreme east-central Charles County, thus inventing a county record on a narrow extension of land that separates Prince George's County from St. Mary's County, and the other at a position arbitrarily located next to their Elvaton site. Moreover, Ernst (pers. comm.) cannot account for his records, so they cannot be allowed. Norden and Zyla also err in stating that Ernst (1972) and Harris (1975) were the only previous authors to report localities for the wood turtle on the coastal plain of Maryland (and by implication the District of Columbia). In addition to the previously discussed sites of Surface (1908), Palmer (1919), Shufeldt (1919) and the marginal Havre de Grace site of Henshaw (1907) and McCauley (1945), there have also been contributions by Conant (1958a), Harris (1969a, 1969b) and Iverson (1986). Conant (1958a) stated that the Natural History Society of Maryland has one or more specimens from Elk Neck, Cecil County. I have searched the NHSM catalogue and can find no entry for *Clemmys insculpta* on Elk Neck, and am unable to verify this claim. Harris (1969a) reported the first record for *Clemmys insculpta* from Prince George's County, for a turtle found at the junction of the Baltimore-Washington Parkway (Md. Route 295) and Md. Route 193, Greenbelt. (This record would have been of use to Norden and Zyla, but they were not aware of it.) However, Harris (1969b), while plotting this record in Prince George's County, erroneously placed it on the Fall Line. Iverson has stated (pers. comm.) that his (1986, 1992) southern Maryland sites were simply based on the maps of Ernst (1972) and Harris (1975).

Some herpetologists may be concerned about the almost total absence of documentation for the records presented by Norden and Zyla. Although the authors use the word "specimen" frequently in their article, specimens, in the strict sense of the word (i.e., a preserved organism in a systematic collection), do not appear to exist. Only in the case of the Mount Rainier turtle, where a photograph accompanies the article, is evidence provided. Several of the turtles were apparently not examined by either author, and in only two of the 12 reports are either of the authors specifically mentioned as having seen them. The two turtles from Clinton (Prince George's County) date long before Zyla's possible involvement with them and one wonders what these records are based on. In eight of the 12 reports no statement is given as to the whereabouts of the "specimen" listed. The names of collectors are not given for four of the nine Prince George's County localities.

I find it impossible to accept that a turtle as large and conspicuous as *Clemmys insculpta* could be as common (i.e., naturally occurring) in the suburbs of Baltimore, Washington, and Annapolis as Norden and Zyla indicate, yet somehow go unnoticed until very recently. Four of their records date from the early to mid-1970s, and seven others were found between 1988 and 1990. [The remaining record (which has conflicting locality data), from 1958, is correct as printed, but the site is based solely on the recollection of a local resident and the turtle's identification was not verified by anyone (J. D. Zyla, pers. comm.). The statement that the "specimen" was brought to the Clearwater Nature Center is erroneous (J. D. Zyla, pers. comm.).] As mentioned earlier the National Museum has no specimens from southern Maryland, nor to my knowledge does any other systematic collection. In this regard, it is significant that at the Patuxent Wildlife Research Center, an 1800-ha tract that lies midway between several of Norden and Zyla's localities, and where professional biologists have made collections and conducted research since the early 1940s, no records of *Clemmys insculpta* exist (Patuxent . . . 1979). Nor do I agree with the authors that "The number of specimens found in that area [southern Maryland] over the years clearly indicates the presence of a viable population . . . ." The lumping of recent, improbable, and far-flung localities, based largely on single individuals in a region of fragmented habitat, and designating them a "viable population" is scarcely proven. Only in the case of the hatchling from Greenbelt has some hard evidence of regeneration been adduced. But even here the locality is suspect, and it is well known that female emydids can store sperm for at least four years and still produce viable offspring (Ewing 1943; Hildebrand 1929). At best I believe Norden and Zyla have provided evidence for a potentially successful introduction of *Clemmys insculpta* at this one locality.

The accurate determination of animal ranges is difficult and complicated by many factors, one being the influence of man. This is particularly true for turtles because of their attraction and susceptibility to collection, and "the propensity of human beings, young people especially, to transport turtles and liberate them far from their natural habitats" (Conant 1958a). As noted at the outset, a

sizable literature deals solely or in passing with the subject of feral turtles in Maryland and the District of Columbia, and I believe the article by Norden and Zyla is an important, if unintentional, contribution to it. Obviously the problem is more complex when the species in question is indisputably a part of the native fauna, as *Clemmys insculpta* is. This species' natural distribution is much more debatable in the Maryland piedmont, and there is also need for elucidation on the Allegheny Plateau. I do not greatly fault the authors for publishing their records; given the number they have gathered, I can understand the urge to do so. What I do not understand is their failure to marshal any sort of argument in the face of a century's worth of contrary evidence.

One other aspect of the note by Norden and Zyla deserves comment. Their article underwent no peer review, or even a proofreading, and was published in a journal completely controlled by the senior author. These practices, unfortunately an expanding tradition at the Natural History Society of Maryland, have been previously discussed and deplored in a more serious context by McCranie and Wilson (1979), and by subsequent authors in this journal. Regrettably their criticisms are being widely ignored.

Acknowledgments.—I thank David M. Hillis and Joseph C. Mitchell for reviewing the article, and Ronald I. Crombie for supplying copies of certain references. Donald C. Forester provided working space, equipment, and helped process the manuscript. Bruce C. Miller also assisted with processing the manuscript.

TECHNIQUES

An Alternative Method For Preparing Skeletons Of Fluid-Preserved Specimens Using Dermestid Beetles

The use of dermestid beetles for skeleton preparation is often preferred because of their efficiency. Techniques for maintaining and using beetle colonies have been developed and reviewed (Anderson 1948; Coleman and Zbijewska 1968; Dirrigl 1989; Hangay and Dingley 1985; Hildebrand 1968; Matthiesen 1989; Sommer and Anderson 1974). Often, preparators wish to make skeletal preparations from material previously preserved in fluid (e.g., formalin, 70% alcohol). This process poses difficulties because the beetles do not feed on fluid-preserved specimens.

De la Torre (1951), Hildebrand (1968), and Hooper (1965) presented procedures for preparing skeletons from fluid-prepared specimens using dermestid beetles. Hildebrand (1968) suggested dipping specimens in cod liver oil or soaking them in bouillon to restore flavor, and offering them in absence of other food. Most recently, Gritis and Brunner (1990) found that use of a "blood solution" produced better results than coating specimens with fat, grease, or cod liver oil.

We developed steps to accompany Hildebrand's (1968) bouillon suggestion. Our steps are similar to those of Gritis and Brunner (1990). The method we present involves preparing beef solutions using bouillon or seasoning packets from instant noodle soups:

1. Prepare beef solution by adding one seasoning packet per two cups of hot water; or one bouillon cube or one teaspoon of instant bouillon per cup of hot water. Mix the solution until all the bouillon or seasoning is dissolved. Enough solution should be made to completely cover the specimen(s). This solution can be made fresh or can be stored for later use. For storage over a prolonged period, we recommend placing the solution in a refrigerator.

2. Skin and flesh out and thoroughly rinse the specimen in cold water. Large specimens may be disarticulated or sectioned appropriately. Remove large pieces of muscle from the bones. Small specimens (e.g., < 100 g) should be placed separately in a small covered container of water to soak for 1-3 days. Larger specimens (e.g., > 3000 g) should be placed in larger covered containers and soaked in water for 1-5 days, changing the water daily. We found that a specimen rinses better when the water covers the entire specimen and cold water is used. Specimens prepared in formalin tend to take almost twice as long for the fixative to wash out as specimens preserved in alcohol.

3. Rinse the specimen a final time with cold water, and submerge in the beef solution. Small to medium (e.g., < 3000 g) specimens should be soaked in the beef solution for at least 1-3 days at room temperature. Remove the specimen and place it on a wire mesh frame over a tray (to catch drainage) and dry under a fume hood. The mesh frame allows air to circulate and the specimen to dry evenly. A tray that is lifted at one end by a large rubber stopper will allow the run-off to collect. It can then be wiped up using a sponge. The hood will remove odors and help prevent the growth of mold which can be disastrous to dermestid colonies. A quick way to tell if a specimen is dried enough is to stick a sharp probe into the flesh. If the probe is clean of fluid when removed, the specimen is ready to be placed into the dermestid colony.

4. All specimens prepared using this method should be identified. This will allow for long term preservation studies and assist researchers who may use the bones for studies (e.g., a trace mineral study).

We found that dermestids will clean most fluid-preserved specimens prepared using this method. We have used this method successfully for reptiles, amphibians, birds, and mammals. Over 100

cat skulls (in formalin) and many anoles (in alcohol) were added to the Vertebrate Collection of The University of Connecticut (UCONN) following the method presented. The effects of bouillon (mostly salt, hydrolyzed vegetable protein, corn syrup solids, sugar, and beef fat) and seasoning (mostly salt, sugar, monosodium glutamate, hydrolyzed vegetable protein, and maltodextrin) solutions on bone (mostly calcium and phosphate) may include the creation of cations that would make the solution become alkaline and could cause bone corrosion. However, for bones placed in the bouillon/seasoning solution for two weeks, we found no evidence of the solution becoming alkaline. Since 1985 and for all specimens prepared using this method, we have found no effects on the preservation of bone using the mixtures of bouillon and seasoning.

We agree with Gritis and Brunner (1990) that many factors (e.g., time in water or solution, condition and cyclic activity of the beetle colony, size of specimen, presence of salt as a main ingredient in bouillon or seasoning) may affect the success of preparing skeletons from fluid-preserved specimens. Use of bouillon or seasoning packets is a successful alternative that offers many advantages. First, it is inexpensive. Bouillon cubes, instant bouillon, or soup packages usually cost under $2.00 at grocery stores. Second, the solutions can be prepared easily any time and stored before and after use. Lastly, this procedure produces practically no odor, and does not stain bones.

Acknowledgments.—We would like to thank the reviewers of this article for their comments and suggestions. Joyce Jarosz-Roth helped with providing information about the possible reactions of bouillon/seasoning solutions with bone. The senior author thanks the Department of Ecology and Evolutionary Biology, The University of Connecticut for continued support of the Vertebrate Collection and for research opportunities.

Retention Of Imitation Satellite Transmitters Fiberglassed To The Carapace Of Sea Turtles

It is difficult to collect continuous data on animals that are wide-ranging, hard to capture, and spend limited time in accessible areas. Sea turtles, for example, are present at the ocean's surface for < 2 hr a day (Byles 1989; Renaud 1990; Standora et al. 1984) and the chance of unaided multiple observations on one or more of these animals is uncommon. Satellite and radio telemetry are two methods of remote sensing available to study various aspects of sea turtle biology (Byles 1988, 1989; Byles and Dodd 1989; Dizon and Balazs 1982; Keinath et al. 1989; Kemmerer et al. 1983; Kolz et al. 1980; Manzella et al. 1990; Renaud et al. 1992; Standora et al. 1984; Standora et al. 1989; Stoneburner 1982; and Timko and Kolz 1982).

Methodology for the attachment of satellite tags (platform transmitter terminals; PTTs) has improved such that PTTs may remain on sea turtles longer than 10 months. However, there are concerns that PTTs may 1) not completely detach from the animal, 2) interfere with breeding behavior, 3) increase the chance of predation on sea turtles, 4) interfere with feeding behavior, or 5) inhibit sea turtle growth. This paper reports on the retention and usefulness of tags fiberglassed to the carapace of Kemp's ridley (*Lepidochelys kempi*) sea turtles and addresses these concerns.

Materials and Methods

Twelve sub-adult Kemp's ridley sea turtles (ca. 32 months old) from the Kemp's ridley Head Start project at the National Marine Fisheries Service (NMFS) Galveston Laboratory were fitted with imitation satellite transmitters (ISTs) (Fig. 1, Table 1). Sea turtles were held individually, indoors in partitioned raceways (2.0 X 2.0 X 0.5 m per turtle) for 16 months. They were fed Purina Trout Chow supplemented with live blue crabs (*Callinectes sapidus*) during the last month of their captivity.

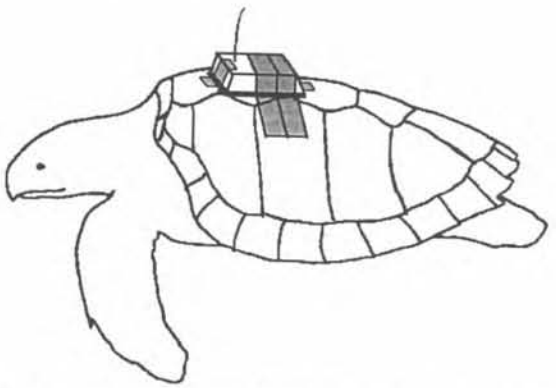

Fig. 1. Schematic of Kemp's ridley sea turtle with imitation satellite transmitter.

Tag Design and Fabrication.—ISTs, fabricated with epoxy resin, were designed after Telonics ST-3 satellite transmitters. They were scaled down in dimension (13 x 8 x 2 cm) and weight (335 g) to accommodate the small size of sea turtles available for experimentation. Scaled-down dimensions were based on the proportion of dimensions of the Telonics ST-3 satellite transmitter to straight carapace lengths (51-60 cm) and widths (48-56 cm) of five previously

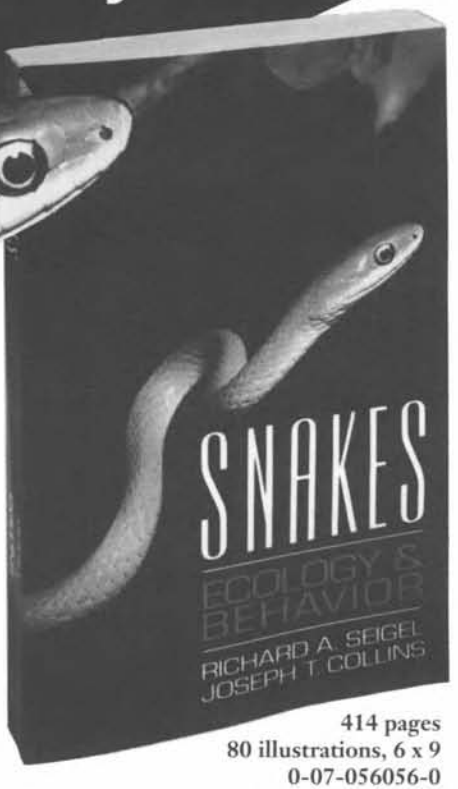
tagged wild subadult Kemp's ridley sea turtles.

Wooden molds were constructed to conform to the above dimensions. Prior to pouring the epoxy resin, molds were coated with PAM non-stick cooking spray to facilitate removal of the finished product. Weight was adjusted with split shot fishing lead to achieve a density equal to that of the ST-3 transmitter. Short plastic cable ties were used to simulate a satellite transmitter antenna. Once hardened, each IST was removed from the mold, sanded to remove rough edges, and weighed and measured to verify that the appropriate specifications were achieved.

IST Attachment.—Given the characteristic dorsal ridge of the juvenile Kemp's ridley sea turtle, IST attachment was performed in three phases. Phase one consisted of shell preparation—cleaning, sanding and drying. Phase two involved construction of a level platform on the sea turtle's back for the IST. Finally, the IST was attached with epoxy resin and fiberglass cloth.

A rectangular clay mold was formed on the sea turtle carapace surrounding the area of IST attachment. A two-part epoxy mixture of HobyPoxy Quick-Fix Formula 4[1] was poured into the mold. Due to the exothermic reaction of the epoxy mixture, the platform was made in multiple layers to prevent excessive heat and discomfort to the sea turtle. Three to five layers were used depending on the height (10–15 mm) of a sea turtle's dorsal ridge. Platforms were 5 cm wide and 11 cm in length. Each layer required approximately 5 minutes to harden. The ISTs were attached by techniques previously used by NMFS for satellite tagging of wild sea turtles. Strips of fiberglass cloth were laid across each IST and allowed to overlap onto the sea turtle carapace. The fiberglass cloth was held in place with epoxy resin. Three separate applications of epoxy and fiberglass cloth were used on each sea turtle. Usually 45-60 minutes of drying was allowed before applying the next layer of epoxy and cloth.

Behavioral Monitoring and IST Maintenance.—Observation of swimming and feeding behavior and documentation of IST sloughing were conducted approximately every two weeks. Conditions considered to be associated with IST sloughing were peeled, chipped, or raised fiberglass cloth. Algal growth on the carapaces of the sea turtles was periodically cleaned off with a medium bristle brush and sponge. This prevented bacterial decomposition of sea turtle food caught in the algae. Removing the algae also facilitated successful assessment of any developments in the sloughing process.



Tag Removal.—The fiberglass cloth was cut with a hacksaw on the front and right sides of the IST. The IST and the remaining fiberglass cloth on the left and rear sides of the carapace were pulled off by hand in one piece. The fiberglass cloth on the anterior and right side of the carapace was easily pried off with a screwdriver.

RESULTS

No ISTs detached during this 16-month study. The epoxy and fiberglass cloth at the margins of all IST attachment points were peeling away from each sea turtle carapace at the termination of this experiment. However 5-7 cm of epoxy and fiberglass cloth remained securely attached to each carapace. Scutes under the IST and fiberglass attachment site were examined after the removal of ISTs. They were comparable to surrounding scutes except for a lighter coloration, likely due to lack of ultraviolet radiation.

Upon completion of the experiment, sea turtles were certified to be in excellent health by a veterinarian. Growth ranged from 2.5 to 8.2 kg/yr (mean = 5.3 kg/yr) and from 3.4 to 8.6 cm/yr (mean = 6.0 cm/yr) in straight length (Table 1). This is similar to other records of Kemp's ridley growth in captivity (Caillouet et al. 1986; Louis et al. 1988).

The most comprehensive survey of snake biology available in a single volume

Authoritative and comprehensive in scope, this important new book offers herpetologists, biologists, and others interested in the study of snakes a broad survey of snake ecology and behavior, as well as extensive coverage of the literature in bibliographic form.

Featuring contributions by leading experts, this definitive reference identifies current areas of research in snake biology and compiles detailed information on important topics that were previously available only in periodicals and journals.

Snakes: Ecology and Behavior reports on exciting new developments in areas such as population genetics ... neurobiology ... functional morphology ... behavioral ecology ... and evolution. Included is detailed coverage of the evolution of mating systems ... thermoregulation ... foraging ecology ... and habitat selection. There is also a wealth of up-to-date information on the stages in the evolution of limblessness ... adaptations to arboreality ... sexual dimorphism ... and conservation strategies.

Filled with illustrations, tables, graphs, and extensive bibliographies, this reference provides major research findings on snake biology that will be invaluable in your current and future work.

GREAT CHILDREN'S BOOK

This Snake is Good is an illustrated adventure novel for children, ages 8–12, based on the real life experience of a child (now Tucson Herp Society member, Bill Copeland) in a summer camp , where ignorance, fear, and a king snake create the setting for a dramatic encounter. A great Christmas gift for young herpetologists. Available direct from the author, and autographed to your special child. $6.25 includes postage.

Discussion

Our experience with satellite tracking suggests that the transmitting package attached to a turtle's carapace usually outlasts the battery life of the PTT. This is based on erroneous data output by PTTs for approximately one week prior to the cessation of data transmission. Therefore, the period of data transmission by a PTT is generally an underestimate of PTT attachment life. The average life of our PTTs on five loggerhead (*Caretta caretta*) and five Kemp's ridley turtles tracked in the Gulf of Mexico or Atlantic Ocean has been 8.5 and 6.5 months respectively. In two cases, however, PTTs have stopped transmitting witin four months without the characteristic week of erroneous data output. Although hard evidence is not available, we suspect that these tags fell off of the turtles. Overall, we feel that PTT detachment is controlled by environmental influences. Sea turtles in our experiment were isolated from each other, held indoors, and thus were not afforded normal environmental contacts such as direct exposure to sun, wave action, weather disturbances, rock jetties, etc. Therefore, we believe that the ISTs would have remained on the sea turtles for several more months.

Evidence suggests that transmitters fiberglassed to the carapace of wild sea turtles sustain impacts during daily activities. One green sea turtle (*Chelonia mydas*) tagged during a radio-tracking experiment at South Padre Island, Texas (Renaud et al. 1992), was recaptured 8 months later without its radio transmitter or sonic tag. In a second study (Renaud et al. 1993) antennas on tags broke off or tags were detached from 5 of 9 green turtles tracked in the vicinity of rock jetties over a 60 day period. Visual observation of these turtles disclosed that every transmitter antenna was bent during the first week of the study. All transmitters were attached in the same manner described in this report.

Sea turtle behaviors (which include swimming through seagrass beds, burrowing in the mud, and wedging under rock overhangs or between rocks) create a harsher environment than that encountered under laboratory conditions. It is not surprising that tags became detached in less time than under laboratory conditions or conversely, that tags in the laboratory did not detach from the sea turtles. We believe that the inshore environment is harsher than the offshore environment and that tags will not last as long on sea turtles inhabiting regions near rock groins or seagrass beds.

It is now hypothesized that PTTs will come off in one piece, preventing a partially detached PTT from being carried by a sea turtle. This is supported by an earlier tagging experience in 1990 (NMFS unpublished data) when a satellite transmitter with its hardened fiberglass attachment was accidentally knocked off a sea turtle in one piece. This hypothesis is further substantiated by the easy removal of ISTs and fiberglass cloth at the conclusion of this experiment. There was no attempt to remove the ISTs by pulling off the entire package in one piece. In hindsight, though, we should have tried this because the ISTs came off very easily once cut on two sides. A few bumps or jolts on rocks or other solid objects in the environment may produce the same result.

If tags fall off juvenile sea turtles within 12 months, they would not interfere with breeding behavior. Small PTT's would probably not interfere with mating turtles, or in the worst case, be knocked off a female turtle during the mating process.

We do not think that PTTs make sea turtles more vulnerable to predation. Tags blend in with the color of the sea turtle carapace and are quickly overgrown with algae to reduce any visual cues of their presence. White barnacles are commonly seen on sea turtle shells in the wild. The high contrast of the barnacle shell would offer more of a visual cue to a predator than a larger PTT with less contrast.

This experiment tested the longevity of packages fiberglassed to sea turtle carapaces. The design of satellite transmitters takes into account swimming and related behaviors (R. A. Byles, pers. comm.). Tags are small compared to sea turtles (<6% body weight) and are relatively streamlined to produce minimal resistance to swimming. The swimming and feeding behaviors of the experimental sea turtles appeared comparable to those of hundreds of captive-raised and wild sea turtles previously observed by the authors in captivity. ISTs did not seem to interfere with daily turtle activity. Sea turtles moved swiftly through the water in their holding tanks and executed quick, sharp turns necessary for the capture of live prey items in the wild. These turtles captured and fed on live crabs while in captivity. Their increase in weight and length during the experiment falls within the growth range of similar-aged turtles (Louis et al. 1988).

In a study similar to ours, Beavers et al. (1991) compared longevity of tag attachment and ease of tagging among 1) polyester resin with fiberglass cast base, 2) epoxy alone, and 3) dental compound with fiberglass cast base. Their choice of tag attachment was dental compound due to quick setting time. No shedding time was given. Tags attached with polyester resin or epoxy remained on the turtles for at least 142 days. No deleterious effects on the sea turtles or changes in sea turtle behavior due to tag attachment were noted by Beavers et al. (1991).

Based on our results, we feel that transmitter packages attached to the carapace of sea turtles are not harmful. Continuous data on sea turtles in the wild is lacking and the use of satellite telemetry is a cost-effective means of collecting such information. If the tags can last for 6–10 months they can provide a wealth of data on sea turtle behavior.

Acknowledgments.—We thank Dr. Richard Henderson, Galveston Veterinary Clinic, for physical examination of sea turtles prior to their release.

[1] When this experiment was conducted, HobyPoxy was the preferred substance for platform construction. Due to variability in the exothermic reaction of this substance it is no longer recommended for use. Now we construct platforms in advance with dental compound, a non-toxic, cold-cure medium. Each platform can be cut with a razor blade to fit the dorsal ridge of any sea turtle just prior to tag attachment. A considerable reduction in the out-of-water time for each sea turtle is achieved by having these platforms made in advance.

Adhesive Trapping II

Bauer and Sadlier (1992) introduced the herpetological community to sampling possibilities offered by mouse glue traps (Woodstream, Inc., P.O. Box 327, Lititz, Pennsylvania 17543, USA) and extolled the virtues of adhesive trapping for sampling arboreal lizards. Since 1988, we have used adhesive trapping to sample a variety of reptiles and amphibians on islands of the western Pacific under a wide range of conditions. Our cumulative sampling experience exceeds 30,000 trap-h (one trap set for one hour = 1 trap-h). Adhesive traps are often the best available sampling method.

While adhesive traps offer a high capture rate, relative ease of use, and some utility for wary species, they do have some disadvantages. Capture rate declines sharply with time in place (Fig. 1); this reduction is probably due to both localized depletion of trap-vulnerable animals and deterioration of the adhesive. Dust, water, debris, and insects will cover the sticky surface of a trap and render it ineffective. Rain almost completely disables a trap, and moisture weakens the backing paper. Glueboards by other manufacturers can be backed with shallow plastic trays, but rain water accumulates in the plastic trays and renders them useless. When we have set plastic and paper-backed traps in alternation (N > 700 trap-h), the plastic-backed traps captured 95% fewer reptiles than the paper traps. Because of rapid decline in trap effectiveness, paper backed traps are rarely useful for more than one 24-h period; their modest cost ($.50/trap when purchased in bulk) justifies replacing them frequently. In countries without a trash removal system, we have found it difficult to dispose of used adhesive traps without the spent traps coming in contact with children or domestic animals. Under these conditions they should probably be buried or burned.

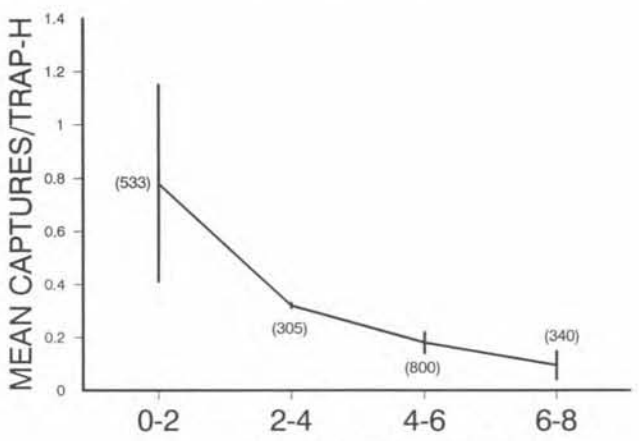

FIG. 1. Decline in success of capture of lizards on adhesive traps following setting, based on daylight captures from single-day ground-trap arrays on Guam (symbols represent catches at respective sets). Error bars are standard deviations of the means for each array (arrays consisted of 8–36 traps). The decline in capture success from 0–2 to 2–4 h after set is not attributable to the normal activity cycle of lizards in this area, which typically reach maximal levels at 1000-1200 h, 2–4 h after initiation of trapping. When trapping was continued for additional days, subsequent mean capture rates did not exceed 25% of the rate achieved during the first two hours.

Glue viscosity is affected by temperature and below 20°C it is challenging to remove delicate lizards without tail loss; an extremely slow, gentle pull is required. Bauer and Sadlier (1992) noted that corn oil dissolves the adhesive and facilitates removal. Robust skinks can usually be removed in excellent condition and without resorting to oil. Geckos, especially those with delicate skins (Bauer et al. 1989), must be oiled for removal. If an unoiled reptile is discovered to have some residual stickiness after removal, it should

be placed in a plastic bag that has been coated with a very light layer of cooking oil. A few drops, well distributed in the bag, is enough to create a usable film; excess oil may cause the sides of the bag to adhere and smother the animal. We have found, however, that some individuals do not survive after being removed from traps and coated with cooking oil.

Nontarget organisms (e.g., crabs, birds, and ants) may accidentally contact or may be attracted to the traps and will remove traps or captured animals. Dogs, cats, and pigs unintentionally carry traps away after stepping on them. The impact of undesired trap contacts are minimized by checking the traps frequently. Over a 24-h period, we typically lose 0–4% of the traps to damage and disappearance. We compensate for this anticipated loss by setting about 20% more traps than required by sampling protocol.

Some species (e.g., *Emoia mivarti*) are relatively difficult to capture because they frequent litter items (e.g., fallen branches) that are not well suited to the use of adhesive traps. Other species (e.g., *Carlia* cf. *fusca*) may be drawn to insects or lizards already adhered to the trap. We have captured lizards and snakes up to a mass of about 100 g (e.g., *Varanus indicus*, *Sphenomorphus muelleri*, and *Boiga irregularis*). In attempting to escape from the traps, these reptiles become further entangled and lose the ability to locomote. Moist amphibians are difficult to trap, although toads can be captured on fresh traps. While no single method catches all species equally (Fitch 1992), adhesive traps catch an unusually broad variety of species, frequently with minimal damage to the specimen.

Reptiles trapped in sunlit areas will rapidly become hyperthermic (Bauer and Sadlier 1992). While we have had minimal success capturing diurnal lizards using small paper tents arched over the traps for shade, nocturnal brown tree snakes (*Boiga irregularis*) are more likely to be captured by traps that are covered by small shelters. Natural shade should be utilized for trapping most species of lizards. We have had excellent success trapping grassland species in the shade of nearby tree rows. The relative success of arboreal versus terrestrial placement will vary among reptile communities. In marked contrast to Bauer and Sadlier (1992), we found adhesive traps much more effective on the ground than in trees. For example, in one seven hour period on Guam we captured 334 skinks on 40 terrestrial traps.

Forty terrestrial traps can be set at 5 m intervals in less than 0.5 h. To facilitate relocation, place the white glueboard covers (which curl upon removal) around a branch above the trap. This procedure also helps to verify the disappearance of traps, especially in dense vegetation or at night. When setting the traps in trees, tying the traps around a trunk or limb by placing a string across the adhesive is less cumbersome than a taping procedure (Bauer and Sadlier 1992). With practice, 40 terrestrial traps can be checked at 15-min intervals and all lizards processed by a single individual. Forty traps and their packaging weigh about 1.0 kg, and occupy a storage space of about 8 x 15 x 25 cm.

Adhesive traps are inexpensive, convenient, highly effective, and usable in areas where drift fences or pitfall traps cannot be placed. Adhesive traps are particularly useful for lizards too wary to allow capture by hand, noose, or rubber banding. For insectivorous reptiles, adhesive traps are somewhat self-baiting. Because they capture an animal only through the animal's own movements, the traps provide an index of locomotor activity. They can also be used for non-lethal sampling of most arboreal or terrestrial reptiles active in patches sheltered from direct sunlight.

Acknowledgments.—We thank the staff of the Denver Wildlife Research Center and especially Mike Fall for pointing out in 1985 the potential application of adhesive boards for the capture of reptiles. We thank A. Bauer for a preprint of his article. A. Bauer, S. Corn, J. Ramsey, R. Hensley, R. Rondeau, and an anonymous reviewer suggested improvements to the ms. Portions of this paper were supported by the Endangered Species Conservation Program, Project E-4 (MJM).

HERPETOLOGICAL HUSBANDRY

Notes On The Captive Maintenance And Feeding Behavior Of A Juvenile Short-tailed Snake (*Stilosoma extenuatum*)

The short-tailed snake (*Stilosoma extenuatum*) is perhaps one of the most secretive snakes of North America. Few specimens have been collected and even fewer have been studied in captivity. Therefore, the habits, including feeding behavior, of this fossorial snake are very poorly known.

Allen and Neill (1953) and Ashton and Ashton (1981) reported that *Stilosoma* primarily consumes small reptiles, namely lizards (including *Scincella lateralis*) and snakes, but Ditmars (1939) and Mushinsky (1984) stated that their captives accepted only small snakes.

Perhaps the most intensive observations on the feeding behavior of this snake were by Mushinsky (1984). He reported that a *Stilosoma* consumed *Tantilla relicta*, but refused three other species of snakes and five species of lizards. Mushinsky also described the loose or weak constricting pattern of this snake and compared it with the boid pattern of constriction as described by Greene and Burghardt (1978).

The following observations on the feeding behavior of a juvenile *Stilosoma* support the contention that this species is primarily ophiophagous, although perhaps not as specialized as described by Mushinsky (1984).

A female *S. extenuatum* (TL=21.5 cm, SVL=19cm) was captured in Gainesville, Florida on 14 April, 1992. An umbilical scar was evident, suggesting that the snake hatched that spring or the previous fall. The snake was housed in a small aquarium with several inches of loose dry sand, and was offered a variety of potential prey, including

Scincella lateralis, centipedes, and small insects. It displayed no interest in any of these items.

On 25 April, a *Scincella* tail was gently placed in the snake's mouth and was swallowed voluntarily. This procedure was repeated on 19 May, 27 May, 3 June, and 9 June. During this time the snake refused to voluntarily consume live or dead skinks placed in its cage.

On 13 May the snake was moved into a simpler cage arrangement consisting of a plastic shoe box with indoor/outdoor carpet as a substrate, a hide box, a water bowl, and several rocks. No supplemental heat or light was provided and the *Stilosoma* was exposed to filtered daylight in quantities naturally occurring in Jacksonville, Florida, USA. Low temperatures ranged from 14.3°C in April to 26.6°C in August and high temperatures ranged from 18.5°C in April to 32.2°C in August. Room humidity ranged from 44% to 92%.

A live newborn *Storeria dekayi victa* (TL=9.0 cm) was placed in the cage on 11 June and was actively pursued, captured, constricted, and consumed in the manner described by Mushinsky (1984). The *Storeria* was grasped posteriorly, wrapped in three coils, and held while the *Stilosoma* advanced its jaws anteriorly. Once the head of the *Storeria* was in the jaws of the *Stilosoma*, the coils were released and swallowing proceeded rapidly.

During the next five months the snake was observed eating twenty times, shed regularly at approximately one-month intervals, and grew 2.3 cm. It consumed seven newborn *S. d. victa*, two newborn *S. d. dekayi*, two newborn *Tropidoclonion lineatum annectens*, three newborn and one juvenile *Virginia striatula*, two newborn *Storeria occipitomaculata occipitomaculata*, two newborn *S. occipitomaculata obscura* and one hatchling *Diadophis p. punctatus*. The size of the snakes consumed without ill effects to the *Stilosoma* ranged from 7.0 cm to 10.15 cm TL.

Seventeen of these snakes were offered alive and three were offered pre-killed, having been frozen and thawed. Three other pre-killed snakes were offered, but were refused. No live snakes were refused except for a 14 cm *D. p. punctatus*, from which the *Stilosoma* appeared to flee.

It soon became apparent that the motion and size of the prey were the most important factors in eliciting a feeding response, although olfactory cues presumably played a role in the recognition of the pre-killed food items. It appeared that normal serpentine locomotion attracted the attention of the *Stilosoma* since pre-killed snakes offered on forceps failed to elicit a feeding response. Minutes after a pre-killed snake was offered and refused, a live snake of the same species was offered and accepted.

We observed, as did Mushinsky (1984), that larger snakes were constricted and smaller snakes were seized near the head and swallowed without constriction. Seventy-five percent of the prey snakes were seized posteriorly and constricted, while the remainder were seized anteriorly and swallowed without constriction.

In no instance was constriction the cause of death of the prey snakes. All were swallowed alive, even after prolonged struggles. The constricting abilities of *Stilosoma* are limited and function as a means of restraining prey.

The actual swallowing process is a rapid side to side motion similar to that of *Lampropeltis*, and the bite appears powerful, visibly compressing the prey. Nevertheless, several prey escapes did occur as observed by Mushinsky (1984). Escapes occurred most frequently when the *Stilosoma* released its bite and began searching for the head of its prey. Generally, the constricting coils were not loosened until the head of the prey was seized. Several prey snakes escaped at least once, but all were recaptured within the close confines of the enclosure.

On 20 September, the *Stilosoma* consumed its largest meal, a live 12.5 cm *Virginia striatula* with a head size and mid-body circumference similar to that of the *Stilosoma*. The *Stilosoma* regurgitated the *Virginia* and died the next day. A necropsy revealed swelling and apparent trauma to the gastrointestinal tract. No parasites were observed.

It is important to note that this snake was a juvenile, and as such, its behavior may have differed somewhat from that of adults of the same species. Regardless of whether any ontogenetic changes occur, these observations have several important implications for future work with *Stilosoma*. They suggest that *Stilosoma* can be maintained in a simple cage setup comparable to that used for commonly maintained species. They demonstrate that at least five species of common, live bearing snakes, some of which may readily be bred in captivity, can be utilized to provide a reliable food source.

Further, these observations reconfirm that very large meals are hazardous to snakes and may result in trauma or death. Lastly, they show that frozen and thawed food items will occasionally be consumed, although live prey is preferred. This allows storage of seasonally available prey species and can assist in parasite control in captive snakes (Rossi 1992).

Acknowledgments.—The authors would like to thank the Florida Game and Fresh Water Fish Commission for granting a permit to conduct this research. We would also like to thank Lyndon Mitchell for his helpful comments.

RECENT POPULATION CHANGES

Apparent Long-Term Decline In Diamondback Terrapin Populations At The Kennedy Space Center, Florida

Diamondback terrapins (*Malaclemys terrapin*) are residents of brackish water habitats along the Atlantic and Gulf coasts of the United States between Massachusetts and Texas (Conant and Collins 1992). Much of the habitat used by diamondback terrapins has been subjected to extensive development, especially in Florida (Ashton and Ashton 1985). The effect of habitat loss and other human disturbance on diamondback terrapin populations is unknown, primarily because few long-term ecological studies have been conducted on the species. Because turtles are long-lived (Gibbons 1987), long-term studies are essential in determining population status.

From 1977 to 1979, I studied the ecology of diamondback terrapin populations at the Kennedy Space Center/Merritt Island National Wildlife Refuge/Canaveral National Seashore (KSC/MINWR/CNS) in east-central Florida (Seigel 1984). The KSC/MINWR/CNS is the largest area of protected habitat along the Atlantic coast of Florida, and is co-managed by the U. S. Fish and Wildlife Service, the National Aeronautics and Space Administration (NASA), and the National Park Service. The KSC/MINWR/CNS harbors considerable suitable habitat for diamondback terrapins, including three large brackish water lagoons (the Indian River, the Banana River, and Mosquito Lagoon), and numerous brackish water marshes and impoundments. In 1992 and 1993 I resampled the diamondback terrapin populations I studied in the late 1970's. This paper reports results from the 1992–1993 surveys.

Studies in the late 1970's emphasized the two largest concentrations of terrapins at the KSC/MINWR/CNS, one located in the northern Indian River along a dike known as "Shiloh Dike," and another in the northern Banana River, centered on a small spoil island ("Island #42"). These populations were estimated at 404 (95% CI = 183–791) and 213 (95% CI = 59–627) individuals, respectively, in 1977–1979 (Seigel 1984). Smaller populations were found in a canal leading into Mosquito Lagoon, the southern end of Shiloh Dike, and along Banana Creek, although population size estimates are not available for these sites. Terrapins also were encountered crossing several roads within the KSC/MINWR/CNS, especially near the Indian River and Banana Creek (R. Seigel, pers. obs.). Seigel (1984) provides a more detailed description of the study sites and techniques used to collect turtles.

Materials and Methods.—During May and August 1992, and April 1993, I resampled *Malaclemys* populations at the KSC/MINWR/CNS using the same techniques used in the 1970's. The Shiloh Dike site was sampled for five consecutive days in May 1992 using small-mesh gill nets to block off a stretch of a narrow canal bordering the dike (Seigel 1984). The Banana River site was sampled on one day each in May and August 1992 and April 1993 by walking in the clear, shallow (< 1 m) waters near Island #42 and other, nearby islands. Attempts were also made to find aggregations of terrapins in canals leading into Mosquito Lagoon, along other areas of the Shiloh Dike, and near Banana Creek during six days in May, two days in August, and six days in April. At all sites, the timing of the sampling, the exact sites sampled, and the sampling procedures were identical to those used in the 1970's.

In addition to my surveys, P. Konen, a graduate student at Florida Institute of Technology, surveyed the Shiloh Dike weekly from mid-March to mid-May 1992 for aggregations of terrapins, which were common during those months in the 1970's (Seigel 1980a). These aggregations frequently contained > 50 individuals in the 1970's, and were very conspicuous.

Results.—During my 1992 surveys, I found only one terrapin, an unmarked adult female in the Banana River. In 1993, a total of 4-6 terrapins were seen in a small brackish water impoundment near the Indian River. No terrapins were seen or captured at Shiloh Dike, the Indian River, Mosquito Lagoon, or Banana Creek during either 1992 or 1993.

Results from P. Konen's surveys along Shiloh Dike resulted in the observation of only a single terrapin. The last large aggregation of terrapins reported from the KSC/MINWR/CNS was seen in August 1986 along the Indian River (T. Lamb, pers. comm.). However, a survey of this site in 1993 showed no terrapins present. My interviews with personnel from the Fish and Wildlife Service, the National Park Service, and the Bionetics Corporation (NASA Life Sciences Support Contractor), indicated that terrapins have been seen only rarely at KSC/MINWR/CNS in recent years. One long-term Fish and Wildlife Service employee reported he had seen only a single terrapin since 1985. Personnel from Bionetics Corp. reported seeing terrapins on only one occasion in the Banana River, despite extensive field work in the area. In addition, no terrapins were observed during U.S. Fish and Wildlife Service seagrass surveys in the vicinity of the Banana River spoil islands during the past two years (C. K. Dodd, Jr., pers. comm.). Finally, neither personnel from Bionetics Corp., the National Park Service, or the U.S. Fish and Wildlife Service reported seeing terrapins crossing roads on the KSC/MINWR/CNS, although one terrapin was found by a local citizen in late August 1992 (R. B. Smith, pers. comm.)

Discussion.—My data suggest that terrapin abundance has declined markedly at the KSC/MINWR/CNS since 1979. Not only were turtles absent almost completely at the Shiloh Dike and Banana River sites, but aggregations in the Mosquito Lagoon canal were also absent. Furthermore, although 45 terrapins were seen crossing two major roads on the KSC/MINWR/CNS between 1973-1979 (L. Ehrhart and R. Seigel, pers. obs.), only one turtle has been seen in recent years, despite extensive travel by local personnel along the same roads (R. B. Smith, pers. comm.).

Another line of evidence for terrapin declines concerns predation on adult terrapins by raccoons, which commonly killed adult terrapins of both sexes when turtles crossed or nested on dike roads in the 1970's (Seigel 1980b). Such predation leaves a record in the form of shells, which were common along at least three dikes in the late 1970's. Despite intensive surveys, no terrapin shells were found in 1992 or 1993, although raccoons were still extremely abundant along the Shiloh Dike area (R. Seigel, pers. obs). Because it is unlikely that raccoons have suddenly stopped eating terrapins for behavioral reasons, the implication is that terrapins are no longer available as prey.

No obvious cause was seen for the apparent decline in *Malaclemys*. The primary habitat changes since 1979 involve the loss of mangrove vegetation along Shiloh Dike, the result of freezing temperatures during the winters of 1983 and 1985 (Provancha et al. 1986), and some subsequent erosion and siltation of the canal bordering the dike. No obvious habitat changes were apparent in the Banana River, Banana Creek, or near the roads where terrapins were seen crossing in the 1970's. Possible causes for the apparent decline include (1) the vegetative changes noted above (which may have led to erosion and siltation near the Shiloh Dike), (2) long-term effects of raccoon predation (Seigel 1980b), (3) incidental catch and drowning in crab traps (Bishop 1983), which are very common in the Indian River and Mosquito Lagoon, and (4) direct mortality from low water temperatures in 1983 and 1985.

Attempting to determine long-term changes in populations of amphibians and reptiles that have not been studied continuously is difficult, especially when only limited time and funds are available for resampling. This case is no exception. Although my data suggest that terrapin populations have declined since 1979, other explanations are possible. For example, terrapin populations may use local

habitats for only short periods, then move on to other sites. Because terrapins often exist in discrete, dense aggregations (Seigel 1984), it is possible that populations are still common at the KSC/MINWR/CNS, but were not observed owing to limited sampling time.

Because of their use of coastal habitats and occurrence in discrete populations, diamondback terrapins may be impacted heavily by habitat development, pollution, and incidental mortality from crab fisheries (Ashton and Ashton 1985; Bishop 1983). Such impacts have led to increased concerns about terrapin populations by state and federal management agencies. For example, all five subspecies of diamondback terrapins in Florida were classified as "imperiled taxa" by a recent survey by the Florida Game and Fresh Water Fish Commission (Millsap et al. 1990). The U. S. Fish and Wildlife Service has initiated surveys of terrapin populations (L. LaClair, pers. comm), as have several states (e.g., Alabama, Mississippi, New York).

I suggest that the apparent declines noted for terrapin populations at the KSC/MINWR/CNS indicate the need for more attention for this species. I hope this paper will encourage state management agencies to address the population status of diamondback terrapins, and I urge researchers with data on population trends to contact both the U. S. Fish and Wildlife Service and their state wildlife agencies.

Acknowledgments.—Special thanks are owed to D. R. Breininger, M. J. Kehl, and R. B. Smith of the Bionetics Corp. for field help and logistical support. I thank the Merritt Island National Wildlife Refuge, the National Park Service, and NASA for supplying permits and granting permission for conducting these studies. Field assistance was supplied by R. Brauman, C. K. Dodd, Jr., J. S. Doody, P. Kain, P. Konen, N. Seigel, B. Seigel, K. Smith, S. Thompson, and J. Young. P. Konen provided invaluable assistance in conducting the spring surveys in 1992. The manuscript was improved by the comments of C. K. Dodd, Jr., J. W. Gibbons, and R. B. Smith. This study was supported by a Faculty Development Grant from Southeastern Louisiana University and by National Park Service Cooperative Agreement No. CA-5320-2-9015.

LIFE HISTORY NOTES

Instructions for contributors to Life History Notes appear in volume 24, number 1.

ANURA

RANA CATESBEIANA (Bullfrog). **CANNIBALISM.** Cannibalism by adult *Rana catesbeiana* is well documented (Bury and Whelan 1984. U.S. Dept. Interior Fish and Wildlife Serv. Resource Pub. 144:1-23). However, its importance in the diet of bullfrogs has less often been considered. Smith (1973. Diss. Abs. Intl. B34[6]:3015) found that cannibalism of immature bullfrogs by adults provided up to 80% by volume of total food in the native Kansas population. We report on a similar high rate of cannibalism in a non-native, high-density population of bullfrogs in a reservoir in southwestern New Mexico.

Wall Lake is a ca. 7–9 ha impoundment on Taylor Creek in the Gila drainage of southeast Catron Co., New Mexico (see description in Fleharty 1967. Southwest. Nat. 12:207-230). The lake has supported a large bullfrog population since at least the late 1950's despite often heavy sport hunting. On 18 July 1978, a sample of 138 adult bullfrogs (90 males, 48 females; 90-191 mm SVL) was collected at Wall Lake and preserved. A stomach contents analysis revealed the following prey items (in order of importance by total percent-volume): newly-metamorphosed and larval *Rana* (87%); aquatic snails (5%); adult and larval aquatic Coleoptera (3%); adult and larval Odonata (3%); and unidentified or other material (2%). Vertebrate remains other than *Rana* included a small unidentified *Thamnophis* sp. and the bones of a small fish.

A total of 57 *Rana* prey items (48 juveniles and 9 tadpoles) was found in 56 stomachs (40.6% of the sample), and 29 of these items (51.8%) were identifiable as *R. catesbeiana*. Although a native ranid occurred in Wall Lake (*R. chiricahuensis*, = *R. pipiens* formerly in Fleharty, op. cit.), we could refer no prey item to this species, which probably had disappeared from the lake by 1978 (CWP, pers. obs.). We therefore considered all *Rana* prey items to be *R. catesbeiana*.

Our results are concordant with those of Hubbard and Schmitt (1977. New Mexico Dept. Game and Fish, unpubl. report) who conducted a stomach contents analysis of introduced *R. catesbeiana* at San Simon Cienega, Hidalgo Co., New Mexico. Of 138 adult bullfrog stomachs in their study, 29.5% contained conspecific prey (juvenile frogs, tadpoles, and eggs) while other vertebrate remains were nearly absent. It is evident that smaller conspecifics can be important food items for adult bullfrogs in some high-density populations (such as at Wall Lake and San Simon Cienega) where other prey are not available.

We thank B. D. Woodward for help in collecting the Wall Lake sample, and J. P. Hubbard and C. G. Schmitt for providing their unpublished data. E. J. Bedrick and T. H. Fritts provided advice on data analysis, and R. D. Jennings, R. E. Robino, and N. J. Scott, Jr. commented on earlier versions of the manuscript.

TESTUDINES

TESTUDO KLEINMANNI (Egyptian Tortoise). **MAXIMUM SIZE.** The maximum documented size is 127 mm for females and 116 mm for males of *Testudo kleinmanni* (Buskirk 1985. 9th International Symposium on Captive Care and Propagation. San Diego. pp. 35-52; Loveridge and Williams 1957. Bull. Mus. Comp. Zool. 115(6):153-557). The record is held by a specimen from Mersa Matruh, Egypt (Flower 1933. Proc. Zool. Soc. London 1933:74-851). Statements that this species can reach the size of 135 mm (Ernst and Barbour 1989. The Turtles of the World. Smithsonian Institution Press, Washington, D.C., 312 pp.) or even 157.5 mm on average (Pritchard 1985. IUCN Freshwater Turtle and Tortoise Newsletter 1:3) are the results of "misreading" the accounts of either Flower (op. cit.) or Buskirk (op. cit.; Buskirk, in litt.). We recently received a small sample (allegedly from a Cairo "pet shop"), of which one female (HNHM uncataloged: BLF 362) clearly exceeds the previously published size record for this species. It has a highly domed, somewhat asymmetrical carapace with well-defined growth rings on the scutes, and lacks the characteristic plastral figure usually present in *T. kleinmanni*. There are 11 marginals on the left and 10 marginals on the right side. The female measured: CL = 129.6 mm, maximum CL = 132.3 mm, maximum CW = 93.5 mm, maximum PL = 112.5 mm, maximum shell height = 72.8 mm (all straight-line measurements taken with vernier calipers).

I thank James R. Buskirk, Oakland, California for encouraging me to publish this record, and reviewing and submitting the manuscript, and Ido Zuri, Tel-Aviv for checking and measuring specimens on my behalf.

LACERTILIA

ANOLIS CAROLINENSIS (Green Anole). **BEHAVIOR.** On 24 September 1992, in the Cherokee National Forest at the confluence of Coker Creek and the Hiwassee River (Hiwassee River Mile 55.8), Polk County, Tennessee, we noted a deserted nest of the bald-faced hornet (*Vespula maculata*). It measured 13 cm in length and 40 cm in circumference. The nest was attached to the woody stem of a climbing hydrangea (*Decumaria barbara*) in a small tree ca. 2 m above the ground. A green anole (*Anolis carolinensis*) was peering from the nest's entrance. The nest was removed intact, placed in a plastic bag, and returned to the University of Tennessee-Knoxville. Dan M. MacDonald and Delia F. Truett removed a male anole (166 mm TL, 60 mm SVL, 5.01 g) from the nest. The nest was then placed in a covered aquarium. The next day a female anole (130 mm TL, 48 mm SVL, 3.30 g), emerged from the nest. Interaction between the paper wasp (*Polistes rubriginosus*) and *Anolis carolinensis* has been reported (Meyerriecks 1960. Copeia 1960:60). This observation suggests that these anoles may have been using hornet larvae as a food resource or the nest as a refugium. We found an active, large group of bald-faced hornets in a similar nest along the Hiwassee River the following week, indicating hornets are active during this season. Whether hornets were present when the anoles invaded the nest is unknown. We thank Arthur C. Echternacht and David A. Etnier for critically reviewing this note.

PARMALEE**, Department of Malacology, Frank H. McClung Museum, The University of Tennessee-Knoxville, Tennessee 37996-3200, USA.

ANOLIS TROPIDOGASTER (NCN). **BEHAVIOR.** The diet of many lizards includes a large proportion of insects and arachnids (Spiller and Schoener 1990. Oecologia 83:150-161), but no cleptoparasitic lizards are known. Here, we describe predation by *Anolis tropidogaster* of a paralyzed spider stolen from a pompilid wasp, *Priochilus captivum* (Fabricius). Females of *P. captivum* provision small vase-like mud nests, built on the ground, with a single paralyzed salticid spider and an egg, oviposited on the spider's abdomen. The larva uses the spider as food.

Observations were made between 0800 and 1100 h on 18 March 1991 (dry season) in a pasture near Rio Perequeté, Playa Leona Corregimiento, Chorrera, Panamá. The female wasp paralyzed an adult female salticid (*Beata cephalica*, 8.5 mm body length) at 0936 h and was dragging it to a nest 80-90 cm away. Suddenly, the wasp dropped the spider and flew swiftly ca. 1 m to attack the head of a male *A. tropidogaster*, standing on the ground. Five stings from the wasp elicited no visible response from the lizard. The wasp then returned to recover the spider. The lizard followed and snatched the spider from the wasp, swallowed it, and ran away. The wasp flew after the lizard, trying to sting it. The lizard hid among dry leaf litter on the ground. While we searched for the lizard, the wasp flew about her nesting site, presumably searching for the missing spider. We captured the lizard. The salticid was the only food item present in the stomach. The wasp escaped capture.

Several aspects of this observation provide insight into the feeding behavior of *A. tropidogaster*. 1) Apparently the lizard selectively preyed on the paralyzed spider, but not on the wasp, a larger prey item (8.5 vs ca. 17 mm). 2) The wasp promptly attacked the *Anolis*, but did not respond to our presence, or that of other lizards. Terrestrial teiid lizards were common in the area. In 40 h of observations we never saw teiids being attacked. Was the *Anolis* recognized by the wasp as a cleptoparasite that exploits the nesting habits of this pompilid wasp? A detailed analysis of the

feeding habits of *A. tropidogaster* is needed.

We thank A. Stanley Rand, Smithsonian Tropical Research Institute (STRI), and E. E. Williams, Harvard for identifying the lizard, for supplying information, and for constructive comments on the manuscript. We also thank STRI for providing research facilities, and A. Mena, Universidad de Panamá, for help in the field.

CARLIA FUSCA (Brown Four-fingered Skink). **DISPLAY BEHAVIOR.** *Carlia fusca* is a diurnally active terrestrial skink and the most frequently encountered scincid in the extensive *Eucalyptus alba* savannahs of southern Western Province, Papua New Guinea. At about 1500 h on 24 May 1986 about 20 km northeast of the village of Wipim, an adult skink ran up the inclined trunk of a dead eucalypt to ca. 40 cm above the ground where it began to wave its tail slowly from side to side. No other skinks nor potential predators were visible. Whether this behavior was directed towards another skink, obscured from view, or towards us could not be determined. We observed this behavior from about 3 m for about 30 s when the lizard stopped displaying. Although numerous other *Carlia fusca* were observed and captured the behavior was not observed again.

Submitted by **MARK T. O'SHEA,** 46 Buckingham Road, Penn, Wolverhampton, WV4 5TJ, England.

VARANUS INDICUS (Mangrove Monitor). **DIET.** Between 1989 and 1991, road killed monitors (N = 18) were salvaged from the island of Rota (Commonwealth of the Northern Mariana Islands) and the Territory of Guam (N = 4). Five additional monitors from Guam (four in the mid-1980's) were incorporated into the data base. All specimens were frozen and later necropsied for stomach contents.

Of the 27 necropsied monitors, 24 were collected in non-urban situations similar to those that Dryden (1965. Micronesia 2:73-76) sampled. Dryden found (expressed as percent occurrence) that arthropods (28), an introduced gastropod, *Achatina fulica* (16.6), rats, *Rattus* sp. (11.5), terrestrial crabs (8.9), shrews, *Suncus murinus* (8.9), earthworms (8.9), and slugs (7.6) formed the bulk of the diet. We found shifts in the percentage occurrence of major prey classes. In our non-urban sample, major prey classes (expressed as percent occurrence) were arthropods (45.5), terrestrial crabs (13.6), scincid and gekkonid lizards and their eggs (27.2), and rats (9.1). Other prey categories in Dryden's sample were scincid and gekkonid lizards and their eggs (3.9), blind snakes, *Ramphotyphlops braminus* (1.3), and wild bird eggs, *Rallus owstoni* (3.8). An additional prey category in our sample was *R. braminus* (4.5).

Terrestrial crabs and rats were found in similar numbers in our study and that of Dryden (op. cit.). Numbers of arthropods and lizards were greater in our study, while introduced gastropods, earthworms, slugs, shrews, and wild bird eggs were not observed. Differences in prey categories were significantly different ($G = 168.2874$, $df = 9$, $P<0.05$). With the exception of earthworms, explanations can be generated for these missing categories. Populations of *A. fulica* have been greatly reduced in the Mariana Islands due to the introduction of the predaceous flatworm (*Platydemus manokwari*) (Muniappan 1987. FAO Plant Prot. Bull. 35:127-133). Populations of slugs have been greatly reduced by the introduction of *Bufo marinus* (Eldredge 1988. Univ. Guam Mar. Lab. Tech. Rep. 88). Shrew populations on Guam are currently very low due to the introduction of the brown tree snake, *Boiga irregularis*, and shrews have apparently never been introduced on Rota (pers. obs.). Recent observations on Guam indicate that monitors prey on wild birds and their eggs (pers. obs.), although they were not recorded as prey items. This predation continues despite very low population levels of birds due to predation by *B. irregularis* (Savidge 1987. Ecology 68:660-668).

Three monitors collected in urban situations (but not compared to Dryden's data) contained domesticated chicken eggs, squid (a common fishing bait), and aluminum butter wrappers.

On Guam, a new prey, *B. irregularis*, appeared in stomachs of *V. indicus* during another study (unpub. data). *Boiga irregularis* (not yet established on Rota) has reached extraordinary densities on Guam (Rodda, Fritts, and Conry 1992. Pac. Sci. 46:46-57).

Losos and Greene (1988. Biol. J. Linn. Soc. 35:379-407) characterized *V. indicus* as an opportunistic predator. The portrait painted here suggests that this is the case in the southern Mariana Islands. Monitor lizards appear to have shifted major prey classes reflecting changes in the available prey base.

We thank E. Taisacan and R. Cruz for assistance in this study. Portions of this study were supported by the Endangered Species Conservation Program, Project E-4, to Guam.

SERPENTES

CHARINA BOTTAE (Rubber Boa). **FOOD.** On 6 August 1991 a *Charina bottae* was collected as it crossed a dirt road in Wallsburg Canyon (40°19'9"N, 111°21'14"W), Wasatch County, Utah. The road runs adjacent to Main Creek, through a narrow riparian habitat consisting primarily of *Acer grandidentatum* and *Populus acuminata*. *Quercus gambelii* and *Artemisia tridentata* are the conspicuous plants surrounding the riparian strip. Within 30 min of capture the snake regurgitated a newborn *Thomomys talpoides* (northern pocket gopher). By the next morning the snake had regurgitated four more newborn *T. talpoides* (Fig. 1), presumably all siblings. The snake measured 400 mm SVL, 52 mm TL, and weighed 46 g after it had regurgitated the five *T. talpoides* ($\bar{x}$ SVL = 80.6 mm). The *T. talpoides* were identified by Clyde L. Pritchett and deposited at the Monte L. Bean Life Science Museum, Brigham Young University (BYU 13151-5). The snake was released at the site of capture.

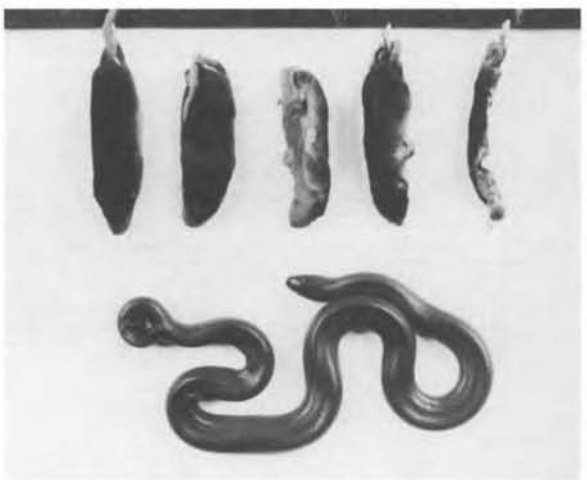

FIG. 1. *Charina bottae* and the five newborn *Thomomys talpoides* it regurgitated.

It is often suggested that *C. bottae* are nest raiders, but Van Denburgh (1922. The Reptiles of Western North America. p. 642) presented the only evidence of this. Van Denburgh (*ibid.*) reported that a *C. bottae* from coastal California had eaten six young mice. This documents *T. talpoides* as prey of *C. bottae* and indicates that these snakes raid nests, at least on occasion. It also demonstrates this species' ability to consume proportionately large meals.

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **DIET**. The following observations were made on 17 May 1992, in Elbert County, Colorado (T7S, R57W, S6). While marking fence lizards (*Sceloporus undulatus*) for a study of territory and home range conducted by John Ferner, an adult female pursued by HMS was struck from ambush by a prairie rattlesnake born the previous fall (it bore only a terminal button). The lizard was released immediately after the strike and it moved about 60 cm from the site of attack before dying (about 8 s after envenomation). Skunkbrush (*Rhus trilobata*) and rocks separated the snake's ambush station from the lizard's final location.

During examination of the dead lizard, HMS placed the carcass on a flat rock adjacent to the post-envenomation path. Photographs were taken, and the lizard was then placed back at its terminal location. While the prey was being photographed, the rattlesnake crawled into a rock crevice about 15 cm from its ambush station, apparently frightened by the observers.

All observers, except for DC, left the area. After about 10 min, the snake emerged from its burrow and began following the exact route taken by the lizard after envenomation. Tongue flicks were systematically directed to the substrate during this process. When the snake arrived at the flat rock mentioned above, many tongue flicks were aimed at the spot where the lizard had been placed, clearly implying that chemical cues were being used by the snake. During the snake's examination of this rock, a disturbance was created by two nearby fossil hunters upon discovering some shark teeth. The snake retreated to the burrow used earlier and another 10 min passed before the animal again emerged. This time the snake moved about 20 cm along the lizard's pre-envenomation pathway before returning to the post-envenomation route. Again the snake examined the flat rock extensively with tongue flicks for about two minutes before moving back to the main trail. After rejoining the trail, the snake moved to the lizard carcass and swallowed it while crawling backward to cover (Fig. 1).

FIG. 1. Yearling prairie rattlesnake (*Crotalus viridis*) swallowing a fence lizard (*Sceloporus undulatus*).

These observations give rise to several hypotheses. First, chemical cues were probably used to recover the lizard carcass (Henderson et al. 1983. Herpetologica 39:75-77). Although numerous studies exist of prey trailing by rattlesnakes, all have involved rodent prey, and we are aware of no previous account of rattlesnakes following lizard trails. Second, the snake appeared to discriminate between the lizard's pre-envenomation and post-envenomation trails, preferring the latter. While this sensory ability has been seen in rattlesnakes preying upon rodents (Lee et al. 1992. J. Herpetol. 26:95-98), we are aware of no previous work showing this with lizard prey. It is interesting that the rattlesnake struck and released the lizard. While releasing is routine when adult rodents are prey (Kardong 1986. J. Comp. Psychol. 100:304-314), lizards are typically held by captive snakes following the strike (DC, pers. obs.). The present rattlesnake was very small and thin, probably not more than 12 g, while the lizard was about 5 g; hence, the relative mass and velocity of the prey probably contributed to its release by the snake. Since previous observations of lizard-holding by rattlesnakes have involved adult snakes, the present case implies that releasing is not uncommon in neonates and yearlings (W. K. Hayes, pers. comm.; Klauber 1956. Rattlesnakes. Univ. Calif. Press, Berkeley, vol. 1, pp. 584, 601; Linscott 1948. Nat. Hist. Notes. 1:3), and that post-strike trailing behavior might be a regular component of their predation upon lizards. Finally, disturbing the snake during its post-strike trailing behavior did not cause the snake to forget its prey, showing the predator was capable of bridging a temporal hiatus created by threatening stimulation.

Submitted by **DAVID CHISZAR**, Department of Psychology, University of Colorado, Boulder, Colorado 80309-0345, USA, and **HOBART M. SMITH** and **RUSSELL DEFUSCO**, Department of Environmental, Population, and Organismic Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

DENDROPHIDION BRUNNEUM (NCN). **REPRODUCTION** and **SIZE.** Data on oviposition and clutch sizes are lacking for most neotropical snake species. On 4 August 1992 the Instituto Nacional de Higiene y Medicina Tropical obtained a female *Dendrophidion brunneum* collected near Sacramento, Cantón Pallatanga, Provincia del Chimborazo, Ecuador (79° 02' W, 02° 10' S). The largely deforested area lies between 1200 and 1500 m above sea level in the western slopes of the Cordillera Occidental of the Andes. Potential natural vegetation is lower montane cloud forest, of which some stands remain.

The snake was gravid and died on 14 August 1992. Dissection revealed six soft-shelled eggs, one of which was damaged during removal. The eggs averaged 28.8 x 12.1 mm in size (28.0-29.9 x 10.4-13.4 mm, N = 5) and had a mean mass of 3 g (N = 5). The dead snake measured 1014 mm TL (SVL = 633 mm, tail = 381 mm) and weighed 51.3 g after the removal of the eggs.

This specimen exceeds the maximum total length of 96 cm reported by Lieb (1988. Herpetologica 44(2):162-175) and is the first record of *D. brunneum* for the province of Chimborazo. It is deposited in the collection of the Instituto Nacional de Higiene y Medicina Tropical (INHMT 2745).

We are grateful to Carl S. Lieb for confirming our identification and reading the manuscript, and to Alfredo Davila, Director General of the INHMT, for institutional and logistical support.

Submitted by **ULRICH KUCH**, c/o Herpetologische Sektion Forschungsinstitut und Naturmuseum Senckenberg, Senckenberganlage 25, D-60325 Frankfurt, Germany, and **ANTONIO FREIRE L.**, Departamento Ofídios, Instituto Nacional de Higiene y Medicina Tropical "Leopoldo Izquieta Pérez," Casilla 3961, Guayaquil, Ecuador.

TRIMORPHODON BISCUTATUS QUADRUPLEX (Zorcuata). **SIZE**. An exceptionally large individual was found dead on the edge of a dirt road in Nicaragua: Rivas; between Parque Nacional Chococente and Río Ochomogo, 18 December 1992. The specimen

(UF 87167) is a female measuring (in mm): total length 1665, head 47, SVL 1402, tail 263 (relative tail length ratio: 0.156), and contains 8 eggs measuring 19-23 mm. Published size records include 104.1 cm for *T. b. vilkinsoni* (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.), and 121 cm for the species in general (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts, 336 pp.). Scott and McDiarmid (1984. Cat. Amer. Amphib. Rept. 353:1-4) did not give actual measurements for the species, but stated that its size "is often greater than 1.5 m in total length." The largest *T. biscutatus quadruplex* was from Honduras (Wilson and Meyer 1985. The Snakes of Honduras. Milwaukee Publ. Mus., 2nd. ed., 150 pp.), measuring 1564 mm TL; the Nicaraguan specimen is 101 mm longer, and thus the largest one recorded for the species.

My visit to Nicaragua was made by invitation of the Minister of Natural Resources, Jaime Incer; permits to collect in Nicaragua were issued by Milton Camacho, Instituto Nicaragüense de Recursos Naturales y del Ambiente (IRENA), which also partially funded the research.

Submitted by **JAIME D. VILLA**, Department of Biological Sciences, Florida Atlantic University, Boca Raton, Florida 33431-0991, USA.

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in volume 24, number 2.

CAUDATA

BOLITOGLOSSA COMPACTA (NCN). COSTA RICA: PUNTARENAS PROVINCE: Canton Coto Brus: Zona Protectora Las Tablas, Finca Jaguar, trail to Panamá, 2000 m. 15 June 1990. Karen R. Lips and Steven D. Werman. Verified by David B. Wake (CRE 5121). Previously known from N slope of Cerro Pando, Bocas del Toro and Cerro Respingo, Chiriquí, Panamá; an extension of 5–10 km west. First record of this species in Costa Rica (Wake, Brame, and Duellman 1973, Los Angeles Co. Nat. Hist. Mus. Contribs Sci. 248:1–19).

Submitted by **KAREN R. LIPS**, University of Miami, Department of Biology, P. O. Box 249118, Coral Gables, Florida 33124, USA.

BOLITOGLOSSA MINUTULA (NCN). COSTA RICA: PUNTARENAS PROVINCE: Canton Coto Brus: Zona Protectora Las Tablas, Finca Jaguar and environs, 1800–2100 m. June 1990–November 1992. Karen R. Lips, Craig Guyer, and Steven D. Werman. Verified by Jay M. Savage (CRE 5351–56, 5234–35, 5121–25); Finca Las Alturas, 15 km NNE San Vito along trail to Cerro Echandi, 1500 m. 1 July 1991. Karen R. Lips and David P. Bickford. Verified by Jay M. Savage (CRE 5285); Jardín Botanico Wilson, Las Cruces, 5 km SE San Vito along Rio Jaca,1100 m. 15–18 February 1992. Karen R. Lips. Verified by Jay M. Savage (CRE 5324). Previously known from Panama on N slope of Cerro Pando, Bocas del Toro, and Cerro Punta, Chiriqui. These specimens extend the range 40 km SW and are the first published records from Costa Rica (Wake, Brame and Duellman 1973, Los Angeles Co. Nat. Hist. Mus. Contrib. Sci. 248:1–19).

Submitted by **KAREN R. LIPS**, University of Miami, Department of Biology, P. O. Box 249118, Coral Gables, Florida 33124, USA.

BOLITOGLOSSA NIGRESCENS (NCN). COSTA RICA: PUNTARENAS PROVINCE: Canton Coto Brus: Parque Internacional La Amistad, near Cerro Frantzius, 1800–2000 m. 14–17 July 1990. Karen R. Lips, Craig Guyer, Sharon M. Hermann. Verified by Jay M. Savage (CRE 5179, 5236, UCR 10720–21); Zona Protectora Las Tablas along Rio Coton, 1700 m. 18 October 1992. Karen R. Lips and Christian Hartmann. Verified by Jay M. Savage (CRE 5357). Previously known from the Cordillera Central of Costa Rica and Volcan Barú, Chiriquí, Panamá. Extends range 125 km SE of nearest Costa Rican locality and 30 km N of nearest Panamanian locality (Hanken and Wake 1982, Herpetologica 38(2):272–287).

Submitted by **KAREN R. LIPS**, University of Miami, Department of Biology, P. O. Box 249118, Coral Gables, Florida 33124, USA.

GYRINOPHILUS PORPHYRITICUS (Spring Salamander). USA: NORTH CAROLINA: Surry Co: 5.3 km NNE Mountain Park, unnamed tributary to Mitchell River. 7 March 1993. Larva. J. C. Beane, A. B. Somers, and Kelly Eanes. Verified by W. M. Palmer. North Carolina State Museum of Natural Sciences (NCSM 32058). New county record; fills gap between Wilkes and Stokes counties (NCSM files).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611–7647, USA, and **ANN BERRY SOMERS**, Department of Biology, University of North Carolina at Greensboro, Greensboro, North Carolina 27412–5001, USA.

NOTOPHTHALMUS VIRIDESCENS (Eastern Newt). USA: Tennessee: Humphrys Co: roadside brook along Tumbling Creek Road, ca. 2 km E Rt. 13. 28 March 1993. C. S. Moran and H. Parker. Verified by B. T. Miller. Middle Tennessee State University (MTSU 54C–58C). New county record (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Thesis, Univ. Tennessee, Knoxville. 290 pp.).

Submitted by **CHRISTOPHER S. MORAN** and **HERSCHELL PARKER**. Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: WISCONSIN: Door Co: Peninsula State Park, Sec .12, T31N, R27E. 6 August 1977. J. Trick. Verified by T. Erdman. Richter Museum of Natural History, University of Wisconsin-Green Bay (UWGB 10, 87); Sec. 16, T31N, R27E. Eft stage. 19 July 1992. D. J. Watermolen. Verified by P. A. Cochran. Milwaukee Public Museum (MPM 25827). New county record, documenting occurrence more than 80 km from nearest locality plotted by Vogt (1981, Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Publ. Mus. 205 pp.), although Eiffert (1963, Journeys in Green Places: The Shores and Woods of Wisconsin's Door Peninsula, Wm. Caxton Ltd., Sister Bay) contains an anecdotal account of a newt in a Door County forest.

Submitted by **DREUX J. WATERMOLEN**, Wisconsin Department of Natural Resources, P. O. Box 10448, Green Bay, Wisconsin 54307, USA, and **GARY S. CASPER**, Milwaukee Public Museum, 800 W. Wells Street, Milwaukee, Wisconsin 53233, USA.

OEDIPINA GRANDIS (NCN). COSTA RICA: PUNTARENAS PROVINCE: Canton Coto Brus: Finca Jaguar, W slope of Cerro Pando, 1900 m. July 1990. Karen R. Lips and Craig Guyer. Verified by Jay M. Savage (CRE 5213, 5322, 5336); Finca Las Alturas, Trail to Cerro Echandi, 1500 m. Karen R. Lips and David P. Bickford. Verified by Jay M. Savage (CRE 5276–5278). Previous records from N slope of Cerro Pando, Bocas del Toro, Panamá (1800–1980 m); extends range 30 km west; first records for Costa Rica (Brame and Duellman 1970, Los Angeles Co. Nat. Hist. Mus. Contrib. Sci. No. 201:1–8).

Submitted by **KAREN R. LIPS**, University of Miami, Department of Biology, P. O. Box 249118, Coral Gables, Florida 33124, USA.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). USA: Tennessee: Scott Co: wooded hillside in Scott State Forest, 150 m N Rt. 297, 0.75 km E boundary with Fentress County. 18 April 1993. C. S. Moran and S. R. Webster. Verified by B. T. Miller. Middle Tennessee State University (MTSU 76C, 77C). New county record (Redmond 1985, A biogeographic study of amphibians in Tennessee, Doctoral Thesis, Univ. Tennessee, Knoxville. 290 pp.).

Submitted by **CHRISTOPHER S. MORAN** and **STEVEN R. WEBSTER**. Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132, USA.

ANURA

CHACOPHRYS PIEROTTI (Chacoan Toad). ARGENTINA: LA RIOJA: Chamical, National Way 38, 25 km S Punta de los LLanos. 22 February 1990. J. A. Scolaro. Verified by J. M. Cei. Museo Regionale di Scienze Naturali, Torino, Italy (MRSN A57). Extends range ca. 200 km NW from previous known distribution (Cei 1980, Amphibians of Argentina, Monit. Zool. Ital., N.S., Monogr. 2:609 pp.). Found in a salt flat related with nearby halophic lagoon systems, during a warm afternoon after a heavy rain.

Submitted by **JOSE A. SCOLARO**, Laboratorio de Herpetologia, Centro Nacional Patagónico, CONICET, Casilla de Correo 69, (9120) Puerto Madryn, Argentina.

HYLA LANCASTERI (Spiny Treefrog). COSTA RICA: PUNTARENAS PROVINCE: Canton Coto Brus: Zona Protectora Las Tablas, W foot of Cerro Pando along headwaters of Río Coton, Finca Jaguar, 1950 m. July 1990–November 1992. Karen R. Lips. Verified by Jay M. Savage (CRE 5208–5212, 5228, 5229–5300). First record for species along Pacific slope drainage in Costa Rica. Previously recorded from Cartago Province, Costa Rica, and Chiriquí and Bocas del Toro Provinces, Panamá. Extends range 100 km W and into Pacific slope drainage of Costa Rica from Panamanian Cerro Pando specimens (Trueb 1968, Copeia 1968(2):285–299; Myers and Duellman 1982, American Mus. Novitates 2752:1–32).

Submitted by **KAREN R. LIPS**, University of Miami, Department of Biology, P. O. Box 249118, Coral Gables, Florida 33124, USA.

TESTUDINES

CLEMMYS MUHLENBERGII (Bog Turtle). USA: NORTH CAROLINA: Surry Co: 5 km NNE Mountain Park. 3 April 1993. J. R. Everhart, J. C. Beane, A. B. Somers, and Surry County Natural Areas Inventory volunteers. Verified by W. M. Palmer. North Carolina State Museum of Natural Sciences (NCSM 32068, 32069, both shells). New county record. Fills part of gap between records from Alleghany and Wilkes counties to the west and Forsyth County to the east (NCSM files). Salvage permits provided by the North Carolina Wildlife Resources Commission.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611–7647, USA, **ANN BERRY SOMERS**, Department of Biology, University of North Carolina at Greensboro, Greensboro, North Carolina 27412–5001, USA, and **J. RICHARD EVERHART**, Route 1, Box 672, State Road, North Carolina 28676, USA.

KINOSTERNON OAXACAE (Oaxaca Mud Turtle). MEXICO: OAXACA: 9 km E Santiago Astata on Rt. 200 (15°58'N, 95°35'W). 19 July 1988; San Pedro Huamelula (16°02'N, 95°40'W). 21 July 1988. John L. Carr and Walter W. Dimmick. Verified by John B. Iverson. A DOR and 5 shells respectively (none collected), documented with slides deposited at USNM. Extends range ca. 90 km ENE of nearest reported localities (Iverson 1986, J. Herpetol. 20:119–123).

Submitted by **JOHN L. CARR**, Conservation International, 1015 18th Street NW, Suite 1000, Washington, D. C. 20036, USA.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). USA: TEXAS: Parmer Co: 16.2 km S Friona on Road 214. 10 July 1992. R. L. Holland and H. M. Smith. Verified by David Chiszar. UCM Color Slides 65–66. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Press, College Station. 434 pp.), leaving but three of the 26 counties in the Panhandle from which it is not yet recorded.

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado, 80309–0334, USA.

LACERTILIA

ANOLIS LINEATOPUS LINEATOPUS (Liguanea Bush Anole). JAMAICA: Manchester Parish: Christiana: Villa Bella, ca. 1000 m. 27 February 1993. Glenn Mitchell and James Lazell. Verified by Ernest E. Williams. MCZ A-11604–6. Extends range 11.5 km NNW Williamsfield and 15.5 km ENE Balaclava into the virtual center of the known range of *A. l. neckeri* (Underwood and Williams 1959, Bull. Inst. Jamaica Sci. Series 9:1–48). Abundant at the site, which consists of a wholly disturbed horticultural and agricultural landscape. Typical of the Liguanea Plain populations, showing no hint of *A. l. neckeri* influence, and thus further complicating the already distressingly complex questions of relationships within the *Anolis lineatopus* group posed by Underwood and Williams (1959).

Submitted by **JAMES LAZELL**, The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835, USA.

EUMECES OBSOLETUS (Great Plains Skink). USA: MISSOURI: Christian Co: Busiek Wildlife Area, Sec. 15, T25N, R21W. 16 April 1993. Stephen G. Thornhill. Verified by Garrett J. Lahey. Bobby Witcher Memorial Collection, Avila College, Kansas City, Missouri (BWMC 04993). New county record; extends known range ca. 55 km (34 mi) NE of the nearest previously-documented locality in state (Toal 1991, Herpetol. Rev. 22:135)

Submitted by **STEPHEN G. THORNHILL**, Burns and McDonnell, P. O. Box 419173, Kansas City, Missouri 64141, USA, and **ROBERT POWELL**, Department of Natural Sciences, Avila College, Kansas City, Missouri 54145, USA.

HEMIDACTYLUS GARNOTII (Indo-Pacific Gecko). USA: FLORIDA: Pinellas Co: Largo, 4 block area 0.29 km N Fla. Rt. 688 and ca. 0.64 km W Fla. Rt. 595, Secs. 1–2, T30S, R15E. 22 December 1992, 19 January 1993, and 4 February 1993. D. M. Crawford and L. A. Somma. Verified by David L. Auth. Florida Museum of Natural History (UF 87231–35). Five adult females captured at night on outside walls of apartment buildings and business establishments in urban surroundings. This species is common at these localities and often seen in company with *Hemidactylus turcicus*. Each adult oviposited two eggs (N=10) during 22–65 days of captivity. Five eggs (UF 87236) were preserved and deposited with the adult specimens. First county record; extends range ca. 117 air km north along Florida's Gulf coast from population in Charlotte County, ca. 198 air km south of record in Citrus County, and ca. 164 air km west of nearest inland populations in Orlando, Orange County (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed., Houghton Mifflin Co., Boston, Massachusetts. 450 pp.; Stevenson and Crowe 1992, Herpetol. Rev. 23:90). This significantly documents the rapid spread of this parthenogenic exotic, which currently ranges along Florida's east coast from St. Augustine in St. Johns County south to Miami in Dade County, throughout much of the Everglades, Florida Keys, and Tortugas in Monroe County, and up the southern portion of Florida's peninsular

Gulf Coast (Steiner and Lamb 1982, Herpetol. Rev. 13:25; Wilson and Porras 1983, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9:1–89; Frankenberg 1984, J. Herpetol. 18:1–7; Voss 1985, Florida Sci. 38:174; Lazell 1989, Wildlife of the Florida Keys. Island Press, Washington, D.C. 253 pp.; Conant and Collins, op. cit.).

Submitted by **DANIEL M. CRAWFORD**, 13521 120th Lane North, Largo, Florida 34648, USA, and **LOUIS A. SOMMA**, Department of Zoology, University of Florida, Gainesville, Florida 32611, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: FLORIDA: St. Johns Co: Madeira Heights, Sec. 21, T7S, R30E. 24 January 1993. Paul Wise. Verified by D. L. Auth. UF 86816. New County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part 2. Lizards, Turtles, and Crocodilians. Windward Publ., Miami, Florida. 191 pp.)

Submitted by **MARK A. WISE**, St. Augustine Alligator Farm, 999 Anastasia Boulevard, St. Augustine, Florida 33811, USA.

LEPIDODACTYLUS LUGUBRIS (Mourning Gecko). NICARAGUA: ZELAYA: Pearl Key (Cayo de Perlas), ca. 75 km NNE Bluefields, coll. 10 Aug. 1991 by J. D. Villa. TCWC 69454–55. Verified by J. R. Dixon. Two voucher specimens out of a large number of lizards seen but not collected. The lizards were active at night throughout Pearl Key (the largest of a series of keys about 5 km off the Atlantic coast of Nicaragua between Tasbuapani and Bluefields) in coconut palms and trees up to 4 m above ground; none were seen on the ground or active in daylight. Eggs were found in what appear to be several communal nests which included two other lizards species. The eggs hatched over about 15–90 days, indicating that they may have been laid over a period of time, probably by more than one female. The species appears to be a recent introduction to the Atlantic coast of Nicaragua (Henderson et al. 1976, Herpetol. Rev. 17:173), where it is rapidly expanding. Although the Keys are uninhabited, they are visited by residents from nearby communities, who probably transport the lizards inadvertently in their canoes. This record extends the range of the species from the nearest known localities, Great Corn Island and Bluefields, by 50 and 75 km respectively.

Submitted by **JAIME D. VILLA**, Department of Biological Sciences, Florida Atlantic University, Boca Raton, Florida 33431–0991, USA.

LEPIDOPHYMA OCCULOR (Jalpan Tropical Night Lizard). MEXICO: SAN LUIS POTOSI: Tamán. 30 March 1989. Rafael Aguilar Cortez. Verified by Robert L. Bezy. Coleccion Herpetológica de la Escuela Nacional de Estudios Profesionales Iztacala (ENEPI 2946). Taken from the walls of a small (ca 2 m deep) cave along the Rio Moctezuma. The species was previously known from four localities in Queretaro and San Luis Potosí (Bezy 1984, Contrib. Sci. Nat. Hist. Mus. Los Angeles Co. 349:1–16). Extends range 45 km E from the area of Landa de Matamoros, and (more significantly) from thorn scrub of the semi-arid Jalpan Valley region (Dixon et al. 1972, Southwest. Nat. 16:225–235) through the eastern front dominated by *Brosimun alicastrum, Dendropanax arboreus, Pithecellobium arboreum, Pouteria glauca*, and *Protium copal* (Rzedowski 1978, Vegetación de Mexico. Editorial Limusa, Mexico, 432 pp.).

Submitted by **JOSÉ L. CAMARILLO R.**, Laboratorio de Investigacion Herpetológica, CYMA, Edificio UIICSE, ENEPI, Universidad Nacional Autonoma de México, A. P. 314, Tlalnepantla, Estado de México, México.

LIOLAEMUS ELONGATUS PETROPHILUS (Stone-loving Lizard). ARGENTINA: CHUBUT: Dique Ameghino Village (43°50'S, 67°20'W). 12 March 1990. J. A. Scolaro. Verified by J. M. Cei. Centro Nacional Patagónico, Colección Herpetológica (CNP-CH 431). New record; extends range ca. 450 km S of previous known distribution (Cei 1986, Reptiles del Centro, centro-oeste y sur de la Argentina, Jus. Reg. Sc. Nat. Torino, Italy, Monogr. 4:527 pp.). Found between stone cliffs on the northern side of the Chubut River canyon.

Submitted by **JOSE A. SCOLARO**, Laboratorio de Herpetología, Centro Nacional Patagónico, CONICET, Casilla de Correo 69, Puerto Madryn 9120, Argentina.

SCELOPORUS VARIABILIS TEAPENSIS (Rosebelly Lizard) MEXICO: OAXACA: municipality of San Juan La Lana, Santiago Jalahui (17°27'10"N, 95°46'09"W). 25–26 September 1990 (MZFC 5414); 15 November 1990 (MZFC 5415); 24 January 1991 (MZFC 5416). Alejandra Rendón. Verified by Oscar Flores-Villela. New municipality record; most northwestern records for the subspecies (Sites and Dixon 1982, Copeia 1982(1):14–27); partially fills hiatus in northwestern part of the state, 80 km NW of locality 19 in Sites and Dixon (op. cit.), and confirms the continuous distribution for this species as proposed by these authors.

Submitted by **ALEJANDRA RENDON ROJAS** and **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de México, Apartado Postal 70–399, México Distrito Federal 04510, México.

SERPENTES

CROTALUS VIRIDIS HELLERI (Southern Pacific Rattlesnake). MEXICO: BAJA CALIFORNIA SUR: 14.8 km (by road) NW (via Mexican Rt. 1) Vizcaino Junction. 4 November 1989. Bryan L. Starrett and Patrick T. Sweeney. Verified by L. Lee Grismer. Natural History Museum of Los Angeles County, Section of Herpetology Photographic Collection (LACM PC1224). Extends range 10 km S and 11.5 km W of nearest known locality, 26.5 km (by paved road) SSW El Arco, Baja California Norte (Ottley and Hunt 1981, Herpetol. Rev. 12:65).

Submitted by **BRYAN L. STARRETT**, Herpetology Section, Phoenix Zoo, 455 North Galvin Parkway, Phoenix, Arizona 85003–3431, USA.

UTACV R–34641. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press, College Station. 434 pp.).

Submitted by **DWIGHT P. LAWSON**, **MICHAEL B. KECK**, and **W. BRYAN JENNINGS**, Department of Biology, The University of Texas at Arlington, Arlington, Texas 76019, USA.

ENULIUS SCLATERI (NCN). COSTA RICA: PUNTARENAS PROVINCE: Canton Coto Brus Las Cruces, 5 km SE of San Vito, OTS Jardín Botanico Wilson (JBW) grounds, 1250 m. Collection date undnown. Luis Diego Gomez. Verified by Jay M. Savage (CRE 5303). Most specimens collected from Atlantic lowlands or Central Valley region of Costa Rica. Third specimen from Puntarenas Province; extends range 55 km ESE from closest locality in Palmar Norte, Puntarenas (Savage and Villa 1986, Herpetofauna of Costa Rica, SSAR Contrib. Herpetol. 3, 207 pp.).

Submitted by **KAREN R. LIPS**, Department of Biology, University of Miami, P. O. Box 249118, Coral Gables, Florida 33124, USA.

HETERODON PLATIRHINOS (Eastern Hognose Snake). USA: Illinois: DeKalb Co: 1 km E Kirtland. 26 May 1954. Jerry Stubbs. Verified by Richard Stupka. Northern Illinois University at DeKalb (NIU-HDW 352). First county record (Smith 1961, Amphibians and Reptiles of Illinois, Illinois Nat. Hist. Survey Bull. 28(1):1–298). Previously reported from adjacent Lee and LaSalle counties.

Submitted by **HARLAN D. WALLEY**, Department of Biology, Northern Illinois University, DeKalb, Illinois 60115, USA.

LAMPROPELTIS TRIANGULUM (Milk Snake). USA: FLORIDA: Okaloosa Co: Sec. 15, T2S, R25W. 23 March 1993. S. L. Collins, K. J. Irwin, and J. T. Collins. Verified by J. E. Simmons. KU Color Slide 10691. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Second ed. Windward Publishing, Miami, Florida. 176 pp.).

Submitted by **JOSEPH T. COLLINS**, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045, USA, **SUZANNE L. COLLINS**, School of Education, University of Kansas, Lawrence, Kansas 66045, USA, and **KELLY J. IRWIN**, 2218 West 2nd Street, Topeka, Kansas 66606, USA.

LEPTOTYPHLOPS DULCIS DULCIS (Plains Blind Snake). USA: TEXAS: Guadalupe Co: railroad by McQueeny Lake dam, 3 km WNW Seguin. 7 April 1990. M. Hogg and D. Stanford. WTSU 13823–4. Jct. Rts. 464 and 1620, 2 km W Seguin. 7 April 1990. D. Stanford. WTSU 14016; Mills Co: Caraway Ranch, 3 km E Goldthwaite. 21–22 April 1977. J. Bertl, R. Brantley, T. Ellerbrook, F. Killebrew, and G. Morris. WTSU 3003, 3240, 3280, 3335–8, 3407–11, 3524–6. All verified by Flavius Killebrew. New county records (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Press, College Station. 434 pp.).

Submitted by **KATHLEEN B. BLAIR**, Department of Biology and Geosciences, West Texas State University, Canyon, Texas 79015–0808, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309–0334, USA.

LEPTOTYPHLOPS DULCIS DISSECTUS (New Mexico Blind Snake). USA: TEXAS: Potter Co: Rt. 1061, 34 km NW Rt. 66 in Amarillo. 30 June 1970. F. Killebrew and Sikes. WTSU 923; Tascosa Road, Amarillo. 5 May–23 June 73. F. McKown and S. Shank. WTSU 1912–5. All verified by Flavius Killebrew. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Press, College Station. 434 pp.).

Submitted by **KATHLEEN B. BLAIR**, Department of Biology and Geosciences, West Texas State University, Canyon, Texas 79015–0808, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309–0334, USA.

MASTICOPHIS MENTOVARIUS MENTOVARIUS (Sabanera). NICARAGUA: ZELAYA: Krukira, approx. 40 km S Puerto Cabezas, 20 Dec. 1991. J. D. Villa, E. J. Petuch, R. Solórzano. TCWC 70207. An adult female with 10 eggs in early stage of development (33–35 mm long), killed while basking on a road at the edge of a gallery forest by a local resident just outside Krukira, who claims that the species is common in the area. Verified by J. D. Johnson. First record of the species in the Departamento de Zelaya and in the Atlantic coast of Nicaragua. The specimen fits well Johnson's definition of *M. m. mentovarius* (Johnson 1977, J. Herpetol. 11:287–309; 1982, Cat. Amer. Amphib. Rept. 295:1–4) in scutellation and color, but falls well outside its distribution map. Previously-known Atlantic coast distribution includes Belize and extreme western Honduras. Extends range approx. 285 airline km from nearest Nicaraguan locality reported by Johnson (1977) and approx. 245 airline km from nearest Honduran locality reported by Wilson and Meyer (1985, The Snakes of Honduras, Milwaukee Publ. Mus., 2nd ed., 150 pp.). Permit to collect in the Miskito Keys National Park issued by Milton Camacho, Instituto Nicaragüense de Recursos Naturales y del Ambiente (IRENA); research partially funded by the Caribbean Conservation Corporation and by IRENA.

Submitted by **JAIME D. VILLA**, Department of Biological Sciences, Florida Atlantic University, Boca Raton, Florida 33431–0991, USA.

RAMPHOTYPHLOPS BRAMINUS (Braminy Blind Snake). MEXICO: VERACRUZ: Municipality of Veracruz, Playa Macambo (19°12'32"N; 96°07'08"W) at sea level. 30 December 1992. Collected by Mario Mancilla. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de México (MZFC 05480). Verified by O. Flores-Villela. Found under log in a trailer park. Previously Mexican records were based on specimens from introduced populations in Baja California Sur (Murphy and Ottley 1979, Herpetol. Rev. 10(4):119), Jalisco (Dundee and Flores-Villela 1991, Herpetol. Rev. 22(1):26), Sinaloa, Michoacán, and Guerrero on the Pacific coast, and inland from Querétaro and Morelos (Dixon and Hendricks 1979, Zool. Verhandel, 173:1–39). Establishes the species in Veracruz, as was suspected by Pérez-Higareda and Smith (1991. Ofidiofauna de Veracruz. Instituto de Biología, Universidad Nacional Autonoma de México Publicaciones Especiales 7, 122 pp.).

Submitted by **FERNANDO MENDOZA QUIJANO, MARIO MANCILLA MORENO**, and **ALEJANDRA RENDON ROJAS**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de México, Apartado Postal 70–399, México, D. F. 04510, México.

RHADINAEA FLAVILATA (Pine Woods Snake). USA: FLORIDA: Walton Co: Sec. 28, T2S, R21W. 27 March 1993. K. J. Irwin and M. Whiles. Verified by J. E. Simmons. KU 220921. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Second ed. Windward Publishing, Miami, Florida. 176 pp.) and partially fills the range hiatus as shown in Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

Submitted by **KELLY J. IRWIN**, 2218 West 2nd Street, Topeka, Kansas 66606, USA, **SUZANNE L. COLLINS**, School of Education, University of Kansas, Lawrence, Kansas 66045, USA, and **JOSEPH T. COLLINS**, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045, USA.

TANTILLA CORONATA (Southeastern Crowned Snake). USA: FLORIDA: Okaloosa Co: Sec. 8, T2N, R23W. 22 March 1993. S. L. Collins, K. J. Irwin, and J. T. Collins. Verified by J. E. Simmons. KU 220922. County record (Ashton and Ashton 1988, Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Second ed. Windward Publishing, Miami, Florida. 176 pp.).

Submitted by **SUZANNE L. COLLINS**, School of Education, University of Kansas, Lawrence, Kansas 66045, USA, **JOSEPH T. COLLINS**, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045, USA, and **KELLY J. IRWIN**, 2218 West 2nd Street, Topeka, Kansas 66606, USA.

The Occurrence Of *Hemidactylus mabouia* On The United States Mainland

The old world tropical house gecko (*Hemidactylus mabouia*) has been introduced to parts of South America and the Caribbean (Kluge 1969; Schwartz and Henderson 1985). This gecko was only recently discovered in the United States from the Florida Keys (Crawl Key) (Lawson et al. 1991). Here we present eight records of *H. mabouia* from peninsular Florida including Everglades National Park.

All collections were made by the authors. Specimens from Everglades National Park were collected under Department of the Interior National Park Service Permit 910039 issued to W. E. Meshaka. Arnold G. Kluge graciously identified and verified specimen AUM 33631. Sexes and snout-vent lengths in mm are provided for all voucher specimens. Specimens collected by BPB and JBH are deposited in Auburn University Museum (AUM). Specimens collected by WEM will be deposited in he U.S. National Museum of Natural History.

Broward Co: Pompano Beach, Day's Inn at Martin Luther King Jr. Dr. and NW 31 Ave. 14 November 1992. AUM 33632. Immature 46 mm. Collected on small building on hotel grounds. Observed four additional individuals on hotel and adjacent small buildings.

Dade Co: South Miami, vicinity of U.S. Rt. 1 & SW 80 Street. 28 August 1990. AUM 33630. Male, 60 mm. Collected on a warehouse wall.

Dade Co: Miami, 2.2 km E Miami International Airport. 8 July 1992. AUM 33631. Male, 59 mm. Observed over 20 individuals on buildings and trees.

Dade Co: Everglades National Park, Royal Palm Hammock. 4 May 1992. USNM 216113. Male, 66 mm. Collected on building.

Dade Co: Everglades National Park, Long Pine Key. 6 July 1992. USNM 216489. Immature, 32 mm. Collected on campground bathroom wall. Frequently observed.

Dade Co: Kendall, vicinity of SW 88 Street and SW 87 Avenue. 9 January 1993. USNM 217057. Female, 52 mm. Collected on house.

Dade Co: Key Biscayne. 2 February. USNM 217330-217331. Immatures, 25 & 27 mm respectively. Collected under board and under bark of Australian pine (*Casuarina* sp.).

Monroe Co: Flamingo. 4 July 1992. USNM 216467. Female, 59 mm. Collected on building wall. Frequently observed.

At many of our sites, *Hemidactylus mabouia* have been repeatedly observed and collected. Our collections include hatchlings, immatures, adults of both sexes, and females containing shelled eggs. These findings strongly indicate that *H. mabouia* is established in the southeastern tip of peninsular Florida.

From our ongoing collections of exotic herpetofauna from south Florida, we have found *Hemidactylus turcicus* to be much less common than *H. mabouia* despite the former species having been known from Key West since 1915 (Fowler 1915) and from Miami since 1936 (Barbour 1936). We offer two explanations for this observation. First, there is evidence that *H. mabouia* is capable of year-round reproduction in south Florida (pers. observ.) as in Brazilian populations (Vitt 1986), whereas *H. turcicus* is a seasonal breeder in both Louisiana (Rose and Barbour 1968) and Texas (Selcer 1986). Greater fecundity in one species could accelerate colonization rates and time of establishment thereby causing it to spread faster than a morphologically similar, less fecund species. Secondly, misidentification of specimens is possible because of superficial resemblance between *H. mabouia* and *H. turcicus*. Without voucher specimens as proof of identification, rates of geographic expansion and geographic range could be attributed to the wrong species.

Our data support the claims that *H. mabouia* is both more common in Florida and may have been in Florida longer than previously thought.

Acknowledgments.—We thank Craig Guyer, Daren A. Herndon, and Kirsten E. Nicholson for their comments regarding this manuscript.

BOOK REVIEWS

Snakes of the *Agkistrodon* Complex: A Monographic Review, by Howard K. Gloyd and Roger Conant. 1990. Society for the Study of Amphibians and Reptiles, Contributions to Herpetology Number 6, vi + 614 pp. 52 plates, including nine ancillary papers by various contributors. Hardcover. US $75. Library of Congress Catalogue Number 89-50342. ISBN 0-916984-20-6.

This book is splendidly produced on 60-pound (text) and 80-pound (black-and-white and color plates) acid-free paper. It is of large format (8.5 X 11") with the text arranged in two columns. A beautiful frontispiece from a watercolor by David M. Dennis depicts representatives of the four genera included in the volume. The work is lavishly illustrated with 32 color plates, 20 black-and-white plates, 60 text figures, and 28 maps. This volume was issued to commemorate the First World Congress of Herpetology held in Canterbury, England, in 1989.

Gloyd and Conant have written a magnificent volume on a widespread and important group of snakes, the *Agkistrodon* complex, which occurs in north temperate and tropical America and Eurasia. These authors have added substantially to our knowledge of these snakes and have masterfully synthesized what is known of the biology of the *Agkistrodon* complex. They treat the four genera of this complex in detail: *Agkistrodon* (10 species), *Calloselasma* (monotypic), *Deinagkistrodon* (monotypic), and *Hypnale* (three species). This book is one of the few herpetological works that can truly be considered a "classic" from the date of its first appearance.

Kraig Adler, who has served as editor for the SSAR Contributions to Herpetology, nicely summarizes the history of the book in the "Editors Note" (pp. iii-iv). As he points out, this monograph has been exceptionally long in its development and completion. A period of some 60 years has elapsed since it was first conceived and executed. In the interim, Gloyd and Conant, individually and jointly, have contributed greatly to herpetology in general and have described or named about a third of all the taxa of the *Agkistrodon* complex (11 of the 34 taxa treated in this monograph). The genus *Deinagkistrodon* and the species *Hypnale walli* were named by H. K. Gloyd. Appropriately, several taxa bear the names of the authors of this monograph, namely, *A. piscivorus conanti* and *A. bilineatus howardgloydi*.

In preparing this book, the authors examined in excess of 6000 preserved specimens (mostly Gloyd), maintained a considerable number of live animals (mostly Conant), and conducted field investigations in the habitats of all four genera (mostly Conant). The authors display an intimate knowledge of these snakes that sets this monograph apart from most others. This work is truly a labor of love.

In some respects, this long-awaited monograph represents a sequel to Gloyd's (1940) "The Rattlesnakes, Genera *Crotalus* and *Sistrurus*: A Study in Zoogeography and Evolution." However, the *Agkistrodon* monograph is more complete, treating taxa in greater detail, and covers a more diverse array of biological topics. The thoroughness of this book is evinced by the 1880 entries in the bibliography.

The preface and introduction are followed by 15 chapters dealing with the systematics of this group, a general summary (in English, Chinese, Japanese, Russian, and Spanish!), a postscript section with comments on various topics, literature cited, an appendix containing Chinese geographical names, and plates (32 black-and-white, 20 color). The last 92 pages contain a collection of nine shorter papers on various aspects of the biology of *Agkistrodon* and related genera.

The Introduction carefully details materials studied, methodology, and provides a useful glossary. A helpful discussion of locality records, place names, and distribution maps is presented.

The section "Taxonomic Status of the *Agkistrodon* Complex" outlines the composition and distribution of the four genera included in the monograph: *Agkistrodon, Calloselasma, Deinagkistrodon*, and *Hypnale*.

Next follows a section providing a checklist and keys to the taxa included in the *Agkistrodon* complex. The keys are remarkably easy to use and allow identification to the subspecies level. A series of systematic sections follow including generic accounts followed by consideration of the various species and subspecies in each genus. Throughout, the text is supported by excellent illustrations of osteology and scutellation. Distribution maps denote the ranges of each taxon.

The order of presentation for subspecies or monotypic species accounts is as follows: scientific name and author, common name, reference to plates or figures, chresonymy, type locality, vernacular names, definition and diagnosis, scutellation, hemipenis, coloration and pattern, form and size, distribution, specimens examined, and ecology and natural history. Each of these accounts is a skillful synthesis of various aspects of the biology of each species. Other miscellaneous sections such as "Erroneous and additional localities," "Range limits and peripheral localities," "Uses by mankind" are added where appropriate. In total, detailed accounts are provided for 34 species or subspecies of the *Agkistrodon* complex, including the problematical *A. affinis*, which may be synonymous with *A. blomhoffii*.

In the chapter entitled "Postscript," Conant treats two new taxa described between the time of Gloyd's death (1978) and the final cutoff date for the monograph (end of 1986). These new taxa are *A. shedaoensis* and *A. halys boehmei*; both are considered valid taxa by Conant. This section also contains interesting discussions on various Asian taxa, field work, taxonomic problems in need of study, and the status of the genus *Gloydius*.

A series of nine ancillary papers at the end of the book covers a wide array of topics and nicely supplements the main body of the book. The paper "Ritualized behavior in *Agkistrodon* and related genera" by Charles C. Carpenter and James C. Gillingham summarizes and describes courtship, male combat, caudal luring, and interspecific defensive behaviors. "Chromosomes of *Agkistrodon* and other viperid snakes" by Charles J. Cole describes the karyotypes of *Agkistrodon, Deinagkistrodon*, and other vipers. In "The fossil history of the genus *Agkistrodon* in North America," Roger Conant discusses the geological time frame in which these snakes made their first appearance and the possible geological events that

influenced the evolution and distribution of this group of snakes in the New World. "The Palearctic species of *Agkistrodon*" by Howard K. Gloyd provides a detailed history of the discovery and often complicated and confused nomenclature of Old World species of *Agkistrodon*. David L. Hardy in "Venoms and envenomation: a selected bibliography of the recent literature on *Agkistrodon* and its allies" provides a comprehensive listing of the literature dealing with the venom properties of snakes in the *Agkistrodon* complex; the alphabetical bibliography is conveniently cross-referenced by species. "General skull, bone, and muscle variation in *Agkistrodon* and related genera" by Kenneth V. Kardong succinctly and clearly describes the dentition, osteology, and myology of these snakes and establishes the taxonomic distinctiveness of the four genera of agkistrodontines. Edmond V. Malnate in "A review and comparison of hemipenial structure in the genus *Agkistrodon* (*sensu lato*)" provides a detailed morphological description of hemipenial structure; interestingly, on the basis of this analysis, *Agkistrodon* and *Hypnale* are paraphyletic (Fig. 2, p. 587). "Immunologic relationships in *Agkistrodon* and related genera" by Sherman A. Minton considers the relationships of these snakes by comparing immunoelectrophoretic and radial immunodiffusion patterns of six species of *Agkistrodon* (*sensu lato*) with other agkistrodontines, other vipers, and colubrid snakes. Minton's research supports the notion that the Asian and American species of *Agkistrodon* (*sensu lato*) form a monophyletic group. Thomas R. Van Devender and Roger Conant discuss the evolution of American *Agkistrodon* in "Pleistocene forests and copperheads in the eastern United States, and the historical biogeography of New World *Agkistrodon*" and attempt to reconstruct the range of the copperhead during the last Ice Age, the Wisconsin Glacial Age, and the Holocene, using paleovegetational maps and the fossil record for *A. contortrix*.

My criticisms of this book are few. Overall, I find the production, organization, writing, and editing to be superior. However, readers would have benefited from a list of illustrations. The discussion of phylogeny and zoogeography perhaps suffers the most from not being subjected to recent ideas in systematics and biogeography. This shortcoming is not lost on Conant, who almost apologetically notes that the approach taken is "old-fashioned." A somewhat dubious phylogenetic tree (Fig. 60) indicates half a dozen or so independent lineages arising from a common "center of dispersal." Perhaps the most perplexing omission in the book is the absence of an index.

These minor criticisms aside, I have only the highest praise for this work. Besides being the ultimate reference on the *Agkistrodon* complex, I appreciate it not only for its scientific merit, but as a work of art. Remarkably, Conant (Conant and Collins 1991) produced another major work within a year of the *Agkistrodon* monograph, namely, *A Field Guide to Reptiles and Amphibians of Eastern and Central North America*.

The Preface, written by Roger Conant, refers to this work as "Gloyd's monograph." Conant meticulously distinguishes between his and Gloyd's contributions to the present volume. The long friendship and productive collaboration of Gloyd and Conant is an inspiration. The herpetological community owes Roger Conant a debt of gratitude for seeing this monumental work through to completion. In this age of flagrant self-promotion, most of us might take a lesson from this most modest man. Gloyd and Conant complement each other in many respects, but share a number of attributes including a conscientious attention to detail, an obvious perseverance, a clear fascination of their subject that is transferred to the reader, an enviable grasp of the literature, and a keen writing ability.

Conant notes the unfortunate fact that papers on natural history have in the last several decades become more difficult to publish in mainstream journals. The *Agkistrodon* monograph provides a wealth of solid natural history information. In assessing the value of this contribution, I can do no better than to quote Greene (1986), who states "Good natural history is a source of timeless, priceless information for the biological sciences. It inspires theory as well as provides crucial data for answers to comprehensive, synthetic problems in ecology, ethology, evolution, and conservation biology." The Gloyd and Conant monograph clearly accomplishes these goals.

Conant also laments "This may well be the last of the generic revisions, in the classic manner first developed by Alexander G. Ruthven." Although no doubt there has been a trend for many modern studies to scorn this approach, I hope that Conant is wrong. There is a need for solid biological works such as that of Gloyd and Conant, and hopefully their contribution will provide the impetus and inspiration for further studies of this kind. However, it is doubtful whether the auspicious combination of persons with such drive and dedication and the opportunity to conduct such research will ever come together again.

Snake Life History in Kyoto, by Hajime Fukada. 171 pages, clothbound. Available from publisher: Impact Shuppankai Co. Ltd., 2-30-14 Hongo, Bunkyoku, Tokyo 113, Japan (price ¥7,000 by international postal order [about US $57]).

This delightful little book summarizes a lifetime's study of Japanese snake populations by Hajime Fukada. Professor Fukada, who was the founding president of the Herpetological Society of Japan and is now retired from Kyoto University of Education, is well known for his detailed investigations of ten species of snakes, most of them studied at a field site just southwest of Kyoto over the period 1954 to 1969. This work was supplemented by some observations at other sites and on captive animals. The list includes seven colubrid species (*Achalinus spinalis, Amphiesma vibakari, Dinodon orientalis, Elaphe climacophora, E. conspicillata, E. quadrivirgata, Rhabdophis tigrinus*) and three viperids (*Agkistrodon blomhoffii, Trimeresurus flavoviridis, T. okinavensis*).

Inspired by Frank Blanchard's studies of snake populations in the 1930s, Fukada has covered abundance and seasonal activity patterns, food habits, reproduction, growth, longevity, body temperatures, hibernation, and a miscellany of other topics including the nuchal gland of *Rhabdophis*, speeds of locomotion on land and in water, and heart rates. There is much here of interest to a general herpetological audience. Although many of the data have been published previously, mostly in Japanese journals, in this book the information is in English (with Japanese abstract) and neatly integrated into a highly readable whole. With 54 figures and 81 tables, there is an enormous amount of basic biological information summarized in a small amount of space.

This book also introduces a clever form of herpetological cinematography. In the free margin of the book there is a series of snake cartoons which, if one thumbs through the book quickly, appear to crawl up and down the page. Finding the correct speed

at which snakes move in table 76, with a little calculation one can figure out how fast to turn the pages to get the silhouette to slither just right! This is Fukada's way to hint at the sheer fun he has had in devoting his life to the study of snakes. The book is a fitting testament to his enviable pleasure.

Michigan Frogs, Toads, and Salamanders: A Field Guide and Pocket Reference, by James H. Harding and J. Alan Holman. 1992. The Michigan State University Cooperative Extension Service, East Lansing, Michigan. 144 pp. Available from: The Michigan State University Museum, East Lansing, Michigan 48824-1045, USA. US $11.95.

This is the third, and last, publication in a general series on the amphibians and reptiles of Michigan. The other two volumes covered the snakes (Holman et al. 1989) and turtles and lizards (Harding and Holman 1990).

Like the preceding volumes, this small book is a practical guide for the general public to aid in identifying Michigan herpetofauna. It is organized in a manner that makes this easy for one with no prior knowledge. A check list of species known to reside in the state is presented that not only lists species, but also gives their higher taxonomy (class, order, family). The common names are given first for each amphibian, making it more useful for the layman. Two pages are provided on how to distinguish Michigan anurans from salamanders. A page is devoted to very good drawings of adult anurans, salamanders and their larvae and important identifying characters used in the text are denoted on these. This is supported by a three page glossary of selected terms. The definitions are to the point and easily understood. Unfortunately, no identification key is provided.

Following are 23 species accounts: *Necturus maculosus, Siren intermedia, Ambystoma laterale, A. maculatum, A. opacum, A. texanum, A. tigrinum, Notophthalmus viridescens, Plethodon cinereus, Hemidactylium scutatum, Bufo americanus, B. woodhousii, Acris crepitans, Pseudacris triseriata, P. crucifer, Hyla versicolor, H. chrysoscelis, Rana clamitans, R. catesbeiana, R. pipiens, R. palustris, R. septentrionalis,* and *R. sylvatica.* The accounts are condensed, containing brief sections on identification (a description of the amphibian), similar species with characters to separate them, distribution (including a map of the distribution in Michigan) and status within Michigan, habitat, and habits (reproductive biology, feeding habits). The serious reader might desire additional information in these accounts but what is presented is concise and accurate, and it was never the purpose of the book to present a complete life history of each species. A brief bibliography is included at the end of the book which includes major books on North American or Upper Midwest amphibians. Also included is a list of available recordings of anuran breeding calls.

After the individual species accounts are sections discussing general aspects of the biology of amphibians (including evolution and fossil history, higher taxonomy, morphology, body functions, foods and feeding behavior, and reproduction), conservation, methods of study, and care in captivity. Like the species accounts, these sections are short, but to the point. Although brief, the table of contents is adequate; however, the lack of an index is a serious flaw.

The book is well illustrated, as it should be for such an endeavor. Each species is covered by color photographs of adults, often larvae and eggs, and some breeding habitats. Among the more interesting photographs are those featuring a spermatophore of *Ambystoma laterale* and a comparison of a normally colored *Rana clamitans* with a blue color-morph. Most of the color photographs are of appropriate size and excellent quality. However, some have been reduced to the point that quality has been lost. Another annoying feature of some photographs is that the figure caption has been printed on the photograph, thus reducing its quality. In some of those photographs which have been reduced in size, the caption is difficult to read. The book is paperback with an adequate binding and good quality paper.

Despite the few problems mentioned above, this is a very good book that admirably fulfills its purpose. The authors should be congratulated for their effort. I highly recommend this publication, and also the other two books of the series, for anyone interested in the herpetofauna of the Upper Midwest.

Biomedical and Surgical Aspects of Captive Reptile Husbandry, 2nd Edition. by Fredric L. Frye, D.V.M., M.S., 1991. Krieger Publishing Company, Inc., PO Box 9542, Melbourne Florida, 32902, USA. ISBN 0-89464-310-X, 2 volumes, 635 pp. US $289.

This edition of Dr. Frye's publication is comprised of two volumes containing 17 chapters, 1850 color photographs, and 180 radiographs. The large size (10" X 14") and weight (5.4 kg) alone are enough to make this an unusual contribution to reptile veterinary literature. The first edition was published in 1981 and was the most complete treatise of reptile medicine available at that time. Since then, at least eight texts and a large number of scientific articles have been published to augment that information. The references at the end of most chapters attest to that. The current volumes are proof that if one has a sincere interest in a field, a flair for photography, and a willing publisher, a niche can be found for presentation of material. There still is no other single source of information about reptile medicine and husbandry that is similar to Dr. Frye's.

Volume I includes chapters on captive husbandry, a practical guide for feeding captive reptiles, fungal, actinomycete, bacterial, rickettsial, and viral diseases, pathologic conditions related to the captive environment, radiology and imaging, hematology as applied to clinical reptile medicine, and applied clinical nonhemic parasitology of reptiles. The chapters in volume II are on ophthalmic conditions, reproduction, developmental anomalies, anesthesia, surgery, comparative histology, euthanasia and necropsy, common pathology and diseases, and antibiotic therapy.

In chapter one, an attempt is made to give a brief overview of the diversity of each order in terms of habitat, feeding strategies, and reproductive characteristics. Little to nothing is said about taxonomic relationships within orders. Chelonians, are referred to as turtles, tortoises, and terrapins and not subdivided further. Nor is any systematic accounting given for families of Squamata or Crocodylia. Thus, the chapter is a perfunctory introduction to taxonomy of the Reptilia. Chapter 2 contains information on

husbandry of captive reptiles. It covers a wide range of topics and is therefore somewhat uneven in its treatment of them. There is reference to very specific thermal requirements of some reptiles which is in contrast to more general descriptions in other portions. Interestingly, this chapter contains phrases such as "agamid" and "lacertid lizard," references to groups of animals that weren't hinted at in the introductory section on taxonomy. There is a nice sequence of photos showing placement of transponder ID chips in various animals. Other photos, such as those of tortoises drinking, aren't particularly relevant. The section on clinical methods seems out of place in this chapter and is very basic information, of little use.

The chapter on nutrition is titled "Nutrition: A Practical Guide for Feeding Captive Reptiles" (although in the table of contents the word Nutrition has been omitted). It includes guidelines and general diet information covering a wide variety of species. A potentially serious shortcoming is the lack of emphasis on feeding balanced diets. Many examples of food items are provided, but no mention is made of the proportions that should make up a diet. Rather than present what would be appropriate levels of nutrients in reptile diets the chapter drifts into the effects of improper nutrition. For instance the section on mineral imbalances starts out as a cohesive discussion of calcium/phosphorus balance but neglects to integrate or emphasize the need for ultraviolet light of the appropriate spectrum even in the face of a balanced diet. It then wanders into the clinical and pathologic appearance of animals with calcium-phosphorus imbalances. Then, rather than include information on how to adjust or formulate diets to include adequate amounts of Ca, P, and D3, the reader is referred to a 1971 publication for information. Sentences such as "With a failure of any one of these factors, the end result is identical in that the calcium is not absorbed from the intestine and the calcium is resorbed" left this reviewer scratching her head for an explanation. An attempt is made to present the syndrome called rickets in a scientific but simplified manner, but ends up reading like double-speak. Although ultraviolet light is mentioned, there is no indication that it is crucial in conversion of 7-dehydrocholesterol to cholecalciferol in the dermis and epidermis. If one didn't already know why vitamin D was important in bone matrix formation one still wouldn't know after reading this description. The author uses the term secondary nutritional hyperparathyroidism to compare it to renal rickets without having introduced it before and then does not explain it. Veterinarians and physiologists won't be at a loss, but considering the level of scientific explanation in this chapter it seems that it is geared more towards the novitiate or student. The section on excessive Vitamin D and A would leave one with the impression that soft tissue mineralization is always a result of oversupplementation, a factor that has been disputed by other researchers. Vitamin D deficiency merits two paragraphs in this section with one of the paragraphs being grossly wrong when it states: ". . . calcium carbonate, and similar natural calcium-rich materials are suitable alternatives" (for vitamin D). In the section on gout there is a non-sequitur paragraph pointing out that the ingestion of D-serine causes renal damage in the American alligator. Several pages are devoted to treatises on invertebrate culture, including techniques for feeding, raising, breeding, and medical treatment of some, all of which should be useful information. This is followed by a section on cultivation of hydroponic grass and legume sprouting. The section on obstipation and constipation contains instructions that could be devastating to snakes if not followed exactly. The use of dioctyl sodium sulfosuccinate is recommended without explaining that if not diluted it can cause severe necrosis of oral tissues of snakes.

Chapter 4, "Fungal, Actinomycete, Bacterial, Rickettsial and Viral Diseases," covers non-parasitic infectious diseases in a brief manner. The introductory section has interesting facts and an overview of general methodology for diagnosis. There is a section attempting to provide insight into reptile immunology which covers the recent literature fairly well. Descriptions of common and some uncommon infectious diseases follow. Noticeably absent, considering the relevance of the disease to large reptile collections, is a discussion of paramyxovirus. Also contained in this chapter is a table listing drug doses.

"Pathologic Conditions Related to the Captive Environment" is a chapter detailing syndromes seen when captive systems have failed. Conditions ranging from dry gangrene of digits in lizards to outright electrocution are covered. It is well documented with photographs.

The chapter on "Radiology and Imaging" was coauthored by Drs. Alex Rubel, Walter Kuoni, and Frye. Good illustrations showing positioning, normal radiographic anatomy, and abnormalities are presented. There are also illustrative materials on magnetic resonance imaging. It in concise and cohesive.

"Hematology as Applied to Clinical Reptile Medicine" covers blood collection techniques with very good photographs showing appropriate positioning. In the section on blood cell counts there is no mention of the techniques of using eosinophil Unopette and RBC Unopette systems for performing WBC and RBC counts, methods that have been used by many zoo labs for years. There are tables listing sizes of RBC's and granulocytes of many different reptiles, red blood cell counts, differential white blood cell counts, and many good photographs of various blood elements from a variety of species. Plasma electrolytes and selected constituents of blood are also listed in table form. All of this information is useful as reference material. It would have been better if table 7-10 indicated whether plasma or serum was used to determine the biochemical (T.P, glucose, urea, uric acid) values, but at least the PCV, and hemoglobin values can be used. The text on hemoparasites is also accompanied by good photographs.

Chapter 8, "Applied Clinical Nonhemic Parasitology of Reptiles," provides a brief section on methods before launching into protozoal parasites. Amoebiasis is well presented, including treatment. Unfortunately, there is no separation between the treatment and control of amoeba section and descriptions of the rest of the possible protozoal diseases. The discussion about cryptosporidium was well done, including the photographs of the appearance of the organisms in a gastric wash. The photographs of various nematode ova would be enhanced by including actual sizes, otherwise they provide useful illustrations for the practitioner. Unlike the previous table on drug doses, the one in this chapter, which lists the common parasiticides, is well referenced. Overall, I would predict that this chapter would be the one most used on a daily basis.

"Ophthalmic Conditions," chapter 9, covers a wide range of syndromes and has many photos to illuminate them, although some are of limited use. There are also references to proprietary names of drugs without ingredients being listed, which could be inconvenient for persons not acquainted with USA veterinary products.

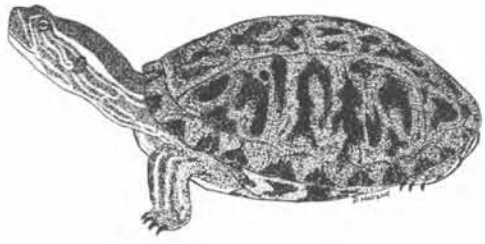
"Reproduction in Reptiles" includes descriptions of courtship and mating behaviors, and discussions on sex determination and identification of sex. Temperature dependent sex determination is well covered prior to presentation of pathological or medical conditions associated with reproduction. The author only refers to using oxytocin for induction of oviposition, neglecting to mention recent work with the more potent product, arginine vasotocin. There are examples of Dr. Frye's folksy, friendly manner in this chapter with statements such as "this is an example of immaculate deception, rather than immaculate conception" and later when describing prolonged intromission uses the phrase *cum staminae serpentis*!

The chapter on developmental anomalies is obviously one of the favorites of the author. It is well illustrated, concise, and covers a broad range of anomalies. There are multiple photographs of most conditions.

Anesthesia in reptiles begins with a good discussion on why hypothermia is not an acceptable method for anesthesia. The description of phencyclidine hydrochloride would be better in an historical perspective section since the drug is no longer available or legal for use. The rest of the chapter provides valuable information on various methods of anesthesia.

The chapter on surgery is well written and has several good sequences of photographs going step by step through various procedures. Surgical concerns that are peculiar to reptiles, such as special instruments, suture patterns, shell cutting and fixation are well discussed. The section on venomadenectomy has a strong emphasis on the reasons for advising against it and for precautions to take subsequent to such surgery.

Taken together, chapters 14-16 cover comparative histology, euthanasia, necropsy, and pathology. The photos included here are by far the best quality in the two volumes and comprise 84 of the 146 pages. Descriptions of the tissue sections and lesions is extensive. Organ systems are thoroughly covered in the histology section. The necropsy chapter has examples of viscera in situ providing good orientation for the reader, and is accompanied by a logical, easy-to-follow techniques section and description of organ appearance and location. The chapter on pathology covers many subjects. Neoplasia makes up the bulk of the written portion. Species affected by particular types of tumors are listed along with descriptions of cases, appearances, and histological characteristics. The organization makes it easy to use as a reference tool.



The last chapter, on antibiotic therapy, is by Dr. Doug Mader. It is well written, contains much factual information, and is well referenced. It includes subjects such as the use of potentially toxic drugs as topical medications, possible sequela, and precautions that should be employed when using them. Two tables are presented, one listing drugs which have had doses determined by pharmacokinetic research, and the other which lists empirically derived doses. This allows the reader to be fully informed as to the realities of the state of the "science" of reptile therapeutics. The theory of metabolic scaling is presented in as understandable a manner as possible. It offers a rational approach for determining new drug dosages. The references for this chapter are easy to access and are all noted in the text.

Overall the text of these volumes is not uniform in style or content. It seems that Dr. Frye hasn't decided who his audience is. In some areas very advanced scientific information is presented. This is contrasted with many areas of very basic information, incomplete discussions, and some misinformation. Some chapters meander from one topic to another without being broken up by subheadings, while others have too many subheadings interspersed in the text. The references at the end of the chapters seem extensive, but would be easier to use if the actual references were listed separately from the additional reading list. It appears that the additional reading citations inflate the reference list by a significant proportion. For instance, in one chapter there were 46 citations in the text, but 89 listed at the end. The concept of "additional readings" would also be more useful if they were divided by subject matter rather than by author. Also, one chapter numbers the references, while the others don't. In the text, there are numerous duplications of information and identical statements repeated in several chapters and there are frequent spelling errors such as ketoconazole being spelled three different ways within a span of three pages.

The photos in these volumes, while larger and more numerous than in previous volumes, have many errors. Some of the photos are identical to the previous edition except enlarged by 25-30%. Fully 15% of the photos are mislabeled, out of focus, repeated elsewhere in the text, not illustrative of the intended lesion, or have incorrect information in the legends. As the author has pointed out, the format of the photo layouts is very inconvenient. Many times the photos are pages away from the accompanying text, and many of the color plates have no page numbers. Some of the photos are on pages that are only half used. Considering the cost of these books it seems that the photos are being used to inflate the page numbers and take up space. The exceptions to these comments are in the chapters on histology and necropsy where the photos are of uniformly high quality and have almost none of the mistakes found elsewhere in the book.

Overall, if one is looking for a broad-based reference to reptile husbandry and medicine that is easy reading this would be the text to get. This is not to say that the work merits the exorbitant price being charged or that it isn't fraught with errors, misstatements, or superficial and irrelevant information. It is unfortunate that Krieger Publishing didn't advertise in advance that identical volumes were going to be sold by another publisher for half the price. In view of that fact, this reviewer is obligated to recommend against buying the Krieger product.

PUBLICATIONS RECEIVED

Systematics of the West Indian Lizard Genus *Leiocephalus* (Squamata: Iguania: Tropiduridae), by Gregory K. Pregill. 1992. The University of Kansas Museum of Natural History Miscellaneous Publication No. 84. 69 pp. Softcover. $4.00 US.

A phylogenetic analysis of the 21 extant and six fossil species in this important West Indian iguanian group. In addition to detailed character descriptions there is a section dealing with biogeography and series of species accounts including type data, synonymies, diagnoses, and remarks. Appendices include an apomorphy list, character state change table, and specimens examined.

Goanna, the Biology of Varanid Lizards, by Brian Green and Dennis King. 1993. New South Wales University Press, Kennsington. 102 pp. Softcover. AUS $19.95 (approx. US $15.00). Available in North America through International Specialised Book Services, 5804 N.E. Hassalo Street, Portland, Oregon 97213-3644, USA.

An overview of the biology of varanid lizards with emphasis on the many Australian species, and on *Varanus rosenbergi* in particular. Chapters deal with taxonomy and phylogeny, feeding, breeding, behavior, thermal biology, respiration, water relations, energy, and conservation. The material presented includes general information as well as tabular and graphical representations of more detailed and specific data, chiefly physiological. The book also features selected references and eight pages of color plates.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in *HR*, but should be submitted to the *Journal of Herpetology* (see inside front cover for Editor's address). *HR* especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of *HR* for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of *HR* under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints.

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes, and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of external reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Life History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in *HR* cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

RWH

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc. RFD 6 Box 1, Lawrence, Kansas 66046. *Herpetological Review* is composed using Microsoft Word and Aldus Pagemaker on Apple Macintosh computers. Camera-ready copy is produced on a Linotronic 230 Imagesetter at a resolution of 1700 dpi at Valley Type & Design, Fresno, California. All rights reserved. No part of this periodical may be reproduced without written permission of the editor.

SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

Catalogue Of American Amphibians And Reptiles

The catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 530	$200.00
INDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages	$5.00
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$5.00
IMPRINTED POST BINDER: (note - two binders are needed for the 505 accounts)	$25.00
INCOMPLETE SET: NUMBERS 1 - 190	$60.00
191 - 410	$70.00
411 - 530	$75.00

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the ***Journal of Herpetology*** (4 issues annually), ***Herpetological Review*** (4 issues annually), and occasional issues of ***Facsimile Reprints in Herpetology***. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1993

Student member	$25.00*	Sustaining member	$60.00*
Regular member	$35.00*	Contributing member	$85.00*

Institutional subscription.....$60.00

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired.). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

NEWSNOTES

Amphibian Species Of The World Update

In 1989, copyright for *Amphibian Species of the World* (Frost 1985) was transferred from the Association of Systematics Collections to the Herpetologists' League (Checklist Committee: R. McDiarmid—Chair, E. Brodie, Jr., J. Campbell, D. Frost, S. Edwards, J. Savage). Frost has steadily updated and augmented the electronic manuscript as a curatorial tool and for eventual preparation of a second edition under the same algorithm used for the first edition. Because synonymies are being added and my time is limited, compilation is slow. Nevertheless, those with curatorial and/or research needs for taxonomic information may request the "working" manuscript on diskette. Due to historical constraints, the manuscript (currently 3.7 Mb) is not in a data-base format, but rather in WordPerfect 5.1; the DOS version for restoring the backup diskettes is 5.0. Please send a $10 handling and diskette fee, along with a letter justifying your need, including a signed statement to the effect that the information will not be resold, or published without attribution or in large sections, as well as a statement of preferred diskette size (if other than 1.44 Mb, 3.5 inch). Write: *Darrel Frost, Compiler—Amphibian Species of the World ed. 2, Department of Herpetology and Ichthyology, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024, USA.*

Request For Slides

The response to our previous request for *Thamnophis* slides to illustrate our book, tentatively entitled *The Garter Snakes: Systematics and Natural History* (Rossman, Ford, and Seigel: University of Oklahoma Press), was beyond our expectations, and we are indeed grateful to all of those who have already generously provided us with slides. Not all the taxa have been covered, however, and we still need good "typical" representatives of the following: *T. atratus aquaticus, T. cyrtopsis ocellatus* (Edwards Plateau), *T. e. eques, T. eques virgatenuis, T. m. melanogaster, T. melanogaster linearis, T. p. proximus, T. proximus rubrilineatus* (Edwards Plateau), *T. proximus alpinus, T. s. sauritus, T. sauritus sackenii, T. scaliger, T. v. validus, T. validus isabelleae, T. validus thamnophisoides*. We do have slides of some of these taxa, but for any of a number of reasons (the coloration isn't "typical," part of the animal is out of focus, etc.) we would like to obtain more satisfactory ones. Finally, if anyone has an outstanding slide of any of the taxa not listed above that he/she would like to see published, we certainly are open to the possibility of "upgrading." Please send slides or inquiries to: *Douglas A. Rossman, Museum of Natural Science, 119 Foster Hall, Louisiana State University, Baton Rouge, Louisiana 70803, USA.*

New Journal Announced

In June 1993, the International Herpetological Symposium, Inc. will begin publication of a new, peer-reviewed journal, *Herpetological Natural History*. It will be devoted to all aspects of natural history of amphibians and reptiles.

The editorial staff of *Herpetological Natural History* seeks original manuscripts that provide new theoretical and/or empirical insights within the broad topics of behavior, ecology, evolution, and life history. Both field and laboratory studies are welcomed. Review papers that synthesize previous studies also will be considered. Papers will be published as either feature articles or notes. A book review section will appear in forthcoming issues.

Herpetological Natural History initially will be published semiannually. Authors should expect accepted papers to be published within 6 to 12 months. Manuscripts and requests for information should be directed to: *Gordon W. Schuett, General Editor, Herpetological Natural History, Department of Zoology & Physiology, University of Wyoming, Laramie, Wyoming 82071, USA.*

Subscription to *Herpetological Natural History* is $20/yr. International surface postage included; air mail quotes provided upon request. Payment, by check or money order in U.S. dollars, should be made out to International Herpetological Symposium, Inc., and directed to: *David Hulmes, Treasurer, International Herpetological Symposium, Inc., 361 Van Winkle Avenue, Hawthorne, New Jersey, 07506, USA.*

Charles Stearns Grant-In-Aid For Herpetological Research At The California Academy Of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due by 15 October 1993, with notification by 1 December 1993. Grantees are expected to complete their Academy visit by 15 September 1994. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

Second World Congress Of Herpetology Travel Awards And Donations

In an effort to obtain travel funding for young herpetologists to attend the upcoming World Congress, the American Society of Ichthyologists and Herpetologists, the Herpetologists' League, and the Society for the Study of Amphibians and Reptiles have applied to the National Science Foundation for an International Travel Grant. Should the total proposal be funded 15 travel awards of $1855 would be available for distribution. NSF's decision on funding the grant may not be known until sometime this summer but in order to make the awards early enough to benefit those attending, applications are being solicited now and will be accepted until 1 August 1993. Awards will be restricted to graduate students, post-doctoral students and young professionals (35 years or less in age) who are members of one of the above herpetological societies.

SSAR Announces a Facsimile Reprint of the Herpetological Classic

THE GILA MONSTER AND ITS ALLIES

by Charles M. Bogert and Rafael Martín del Campo

with a new preface by Charles M. Bogert and a retrospective essay by Daniel D. Beck

•

THIS MONOGRAPH, FIRST PUBLISHED IN 1956, IS STILL THE ONLY comprehensive treatment of the genus *Heloderma*, which comprises the world's only venomous lizards. The book covers all aspects of the animals' biology and venomology. (CONTENTS: classification and distribution; food and feeding habits; bodily functions, behavior, and activities; life history; ecology; venom apparatus and the venom and its effects; bites inflicted on humans; helodermatids and humans; and a bibliography.) Numerous figures, maps, and tables are included, as well as 20 plates of photographs of helodermatid lizards and their habitats.

For this reprint, Charles M. Bogert prepared an extensive and wide-ranging preface (his last scientific contribution before his death in 1992) that gives the history of his collaboration with Rafael Martín del Campo in writing the original book. This preface provides information that is intended to update the book in the areas of fossil history and distribution; the origin, evolution, and dispersal of venomous lizards; the evolution of dentition and venom apparatus; the role of venoms in food acquisition and defense; and the evolution of venomous squamates.

The book also includes a retrospective essay by Daniel D. Beck, author of the most recent studies on the ecology and behavior of *Heloderma*, which evaluates the Bogert and Martín del Campo monograph. Dale Belcher has compiled a comprehensive index.

The color frontispiece is copied from a watercolor of a Gila monster drawn by the noted wildlife artist, David M. Dennis. A special edition of this print, suitable for framing (measuring 9 by 11 inches) and *limited to 100 numbered copies*, is available; these have been *individually signed* by Charles Bogert and David Dennis.

Specifications: 282 pages, 4 portraits of authors, 58 photographs, 35 figures, 5 tables, 2 maps. Clothbound in library-grade buckram, format 7 by 10 inches. To be published August 1993.

***HELODERMA SUSPECTUM* COPE. 1869**
From a Watercolor Painting by David M. Dennis. 1982

TO ORDER

Send orders to the SSAR Publications Secretary, Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103, USA (*telephone* 314-658-3900 or -3916; *fax* 314-658-3117). Make checks payable to "SSAR"; receipt on request only. Overseas customers must make payment in USA funds. Orders may be charged to MasterCard or VISA (account number and expiration date required); a 5.25% bank charge will be added.

BOGERT AND MARTÍN DEL CAMPO: GILA MONSTER AND ALLIES
- Price to SSAR members before August 1, 1993 ..... US$30
- Price to Institutions and Non-members $38

(*Postage*: Add $2 in USA, add $4 for other countries.)

GILA MONSTER PRINT, signed and numbered, postpaid $25

Those wishing to apply should submit: 1) a statement of their present academic or employment status (e.g., Graduate Student at the University of Illinois; Assistant Professor of Zoology at the University of Tennessee); 2) an abstract of a talk or poster which they plan to present at the Congress; 3) a statement of their need of assistance from a supervisor or department head; 4) other relevant materials (e.g., letter of invitation to participate as a speaker or convener of a symposium). Applications will be judged by a committee of three (one representative from each society). Send applications to *International Travel Grant, U.S. Fish and Wildlife Service, MRC 111, National Museum of Natural History, Washington, D. C. 20560, USA.*

At present, any travel awards are contingent on the aforementioned International Travel Grant being funded by NSF. However, organizations and individuals are encouraged to send additional donations for this purpose. Checks should be made out to the Herpetologists' League and earmarked for World Congress Travel Awards and sent to the above address. The selection committee will award all funds received.

Poster Commemorates Jamaican Iguana Survival

The Fort Worth Zoo is offering a beautiful full-color poster of the Jamaican iguana, *Cyclura collei*, which was unveiled at the recent International Symposium and Workshop on the Conservation of the Jamaican Iguana held in Kingston, Jamaica, 22-24 February 1993. The poster is being distributed in Jamaica to heighten public awareness for the plight of this critically endangered lizard. Once feared extinct, the Jamaican iguana was rediscovered in 1990, and a small remnant population still clings to existence in the undisturbed forests of the remote Hellshire Hills. Superb in color quality, this 17 x 22 in. poster features three photographs of the Jamaican iguana and its habitat.

A limited number of posters are available for $10 each plus $2.50 for postage and mailing tube. Proceeds generated by the sale of the posters will directly support the ongoing field research and conservation efforts in Jamaica. To order please send a check or money order for $12.50 payable to the FORT WORTH ZOOLOGICAL ASSOCIATION. Mail to: *Rick Hudson, Reptile Department, Fort Worth Zoo, 1989 Colonial Parkway, Fort Worth, Texas 76110, USA.*

MEETINGS

Societas Europaea Herpetologica 7th Ordinary General Meeting

The Societas Europaea Herpetologica (S.E.H.) will hold its 7th Ordinary General Meeting 15-19 September 1993 in Barcelona, Spain. The meeting site will be the Facultat de Biologia, Universitat de Barcelona. Scheduled plenary lectures include I. Darevsky (*The rock lizards of the Caucasus: the present state of the problem*), J. W. Arntzen (*European newts: a model system for evolutionary studies*), G. Mancino (*Cytogenetics, developmental biology and evolutionary biology in amphibians*), E. Olmo (*Results and perspectives in the study of the karyology of scincomorphs*), L. F. López-Jurado (*Origin, colonization, adaptive radiation, intrainsular evolution and specific substitution processes in the fossil and living lizards of the Canary Islands*), F. B.

SSAR Meeting Highlights

Dates: 7–12 August 1993
Place: Indiana University, Bloomington, Indiana

Keynote Lecture: "Feeding Strategies of Monitor Lizards," by Walter Auffenberg (Florida State Museum). An in-depth, illustrated lecture on the behavior and ecology of the Komodo, Gray's, and Bengal monitors.

Symposium: "Reptilian Behavioral Ecology: A Tribute to Charles C. Carpenter." *Organizers*: James Gillingham and Thomas Jenssen. *Participants*: Robin Andrews, Gordon Burghardt, Geoffrey Carpenter, David Chiszar, William Cooper, Justin Congdon, David Duvall, Gary Ferguson, Neil Ford, Brent Graves, Neil Greenberg, Victor Hutchison, Beth Leuck, Jeffrey E. Lovich, James B. Murphy, Catherine Marler, Joseph Macedonia, Matthew Rand, Stephen Secor, Judy Stamps, Richard Tokarz, and Kent Vliet.

Symposium: "Vision and Visual Cues in the Behavior of Amphibians and Reptiles." *Organizers*: Richard King and John B. Phillips. List of Speakers not yet finalized.

Herpetological Travelogue Slide Shows: Aaron Bauer (Australia, New Zealand, and New Caledonia), Stephen D. Busack (Spain), Thomas Fritts (Galapagos Islands), and C. J. McCoy (Belize). 30-minute, profusely illustrated lectures.

Oral and Poster Presentations: Several concurrent sessions each day. Abstract form in *Herpetological Review*, December 1992 issue, page 97.

Student Paper Awards: Seibert Prizes to be awarded to the two best student papers ($250 first prize, $150 second prize).

"The Great Reprint Scavenge." (For Students Only!). Professionals are asked to clear unwanted duplicate reprints out of their offices (and get free raffle tickets as a "thank you"). Only students will be permitted to sort through the stacks.

Audiovisual Shows: "Herps of the West" (newly updated), "Amphibians of the Appalachians" (updated 1992), and "Herpetology Past and Present."

Field Trips: "Herping with Joe Collins."

Social Activities: Welcoming Reception, the Annual SSAR Auction, Gourmet Beverage Tasting, local tours, and raffle.

Exhibit: Tour of the Indiana University Axolotl Facility, a national facility founded by R. R. Humphrey that breeds and maintains genetic stocks of axolotls for research and teaching.

Live Exhibit: Herps of the Region (Sponsored by the Hoosier Herpetological Society).

Costs: Registration: $50 student, $70 regular; after 15 June, $70 student, $95 regular. Lodging at Indiana University Union (meeting site); $55/day (single) to $88/day (4 persons/2 beds). Air-conditioned dorms are $18/day (double occupancy) and $23.50/day (single occupancy).

Further Details, Call for Papers, and Abstract Form: See the December 1992 issue of *Herpetological Review* (page 97) or on request from Craig E. Nelson, Department of Biology, Indiana University, Bloomington, Indiana 47405 (telephone 812-855-1345, fax 812-855-6705).

Sanchiz (*Phylogenetic and faunistic history of the European batrachians*), and S. Renous (*The ontogeny of locomotion in marine turtles*).

Workshops include Genetics and Systematics, Marine and Freshwater Turtles, Conservation, Biogeography, and Ecoethology. A field excursion to the Parc Natural dels Aiguamolls de l'Empordà is planned; this is a wetland area located northeast of the Iberian Peninsula 150 km from Barcelona.

For registration information, contact: *BRP - Barcelona Relaciones Públicas, Edificio Layetana, C/. Pau Claris, 138, 7.°, 4.a, E-08009, Barcelona, Spain. Tel. (3) 215 72 14, FAX (3) 215 72 87.*

ARTICLES

Where's Waldo (And The Snakes)?

Estimates of relative abundance of animals are often based on visual search methods such as transect counts or time-constrained searching (Campbell and Christman 1982). If different searchers are used to count animals in each of the areas under study, it is tacitly assumed that the searchers do not vary among themselves in their ability to detect the target species. While ornithologists have proposed numerous methods to correct for interobserver differences (Ralph and Scott 1981), this problem generally has been ignored by herpetologists (Jones 1986). For example, a recent symposium volume (Szaro et al. 1988) included eight papers on reptiles and amphibians that utilized visual search methods to determine relative abundances, but I found no mention in any of their methods sections of tests, experimental design modifications, or statistical corrections for interobserver variability.

Snakes usually occur at such low densities, and surveys are so limited in number, that it is difficult to statistically identify the sources of variation in detectability (Fitch 1987; Turner 1977). Brown tree snakes, *Boiga irregularis*, can reach densities in excess of 50 snakes/ha (Rodda et al. 1992), and we have been able to amass hundreds of censuses for some transects in Guam. In visual sampling of the brown tree snake, interobserver variability is one of the strongest identified sources of variability in census counts (Rodda and Fritts 1992). Thus, we can statistically adjust for the differences among searchers in their abilities to find snakes. However, it takes several months of calibration surveys to quantify each observer's bias, and the calibration results have shown that some observers are relatively ineffective for snake searching. Therefore, it would be useful to have a simple method for predicting the abilities of snake searchers. In this paper I describe one potential screening method (hereafter called the Waldo test) and compare its assessment of visual searching ability with relative snake sighting ability.

The Waldo test uses drawings created for entertaining children with visual searching tasks (Handford 1988, 1989). Waldo, a boy with distinctive glasses and a red striped shirt and hat, is located at an unpredictable location on drawings that include many other colorful people and objects. Using a standardized set of written instructions, I asked snake searchers with known snake detection proficiencies to determine the amount of time it took them to find the mildly cryptic figure (Waldo) in each of the drawings. If a participant had seen a drawing before, I discarded that trial. This eliminated only two of 184 reported times (each of eight searchers found Waldo in 23 drawings). To control for order of presentation effects, the drawings were searched in a fixed order. Because drawings varied in complexity, I ranked the times for each drawing independently, and then normalized the ranks using the Blom method (SAS Institute 1988) before determining the mean normalized rank for each searcher.

The eight searchers had each logged at least 25 h of visual snake searching, distributed irregularly over the 14 best-studied transects for the brown tree snake in Guam. During the 692 h of searches (1988-1992) 1117 snakes were captured. The 236 individual nightly capture totals were weighted by the number of search hours they represented and subjected to a two-way analysis of variance. The two factors considered were searcher and transect-year (each transect-year combination was considered separately to accommodate progressively changing population densities). The searcher effect was highly significant ($F=4.76$, $df=7,199$, $P=0.00006$). When adjusted for the varying mix of transects searched, the least squares fit to the model for each searcher's average sighting rate was correlated with their mean scores on the Waldo searches (Fig. 1; $r=0.693$, $df=6$, $P=0.057$).

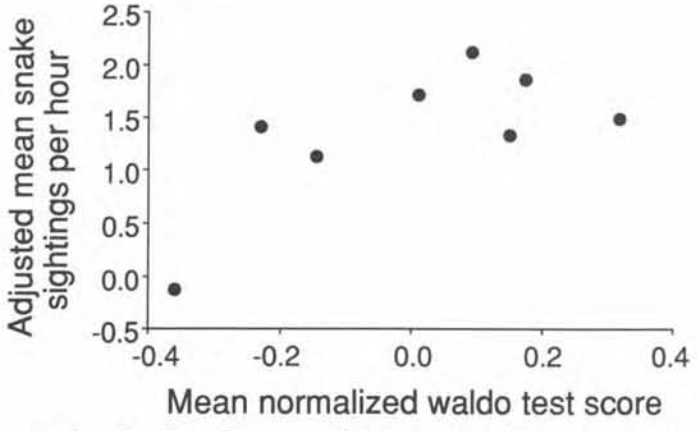

FIG. 1. Correlation between performance on the Waldo test and snake sighting rate ($r^2=0.48$, $P=0.057$).

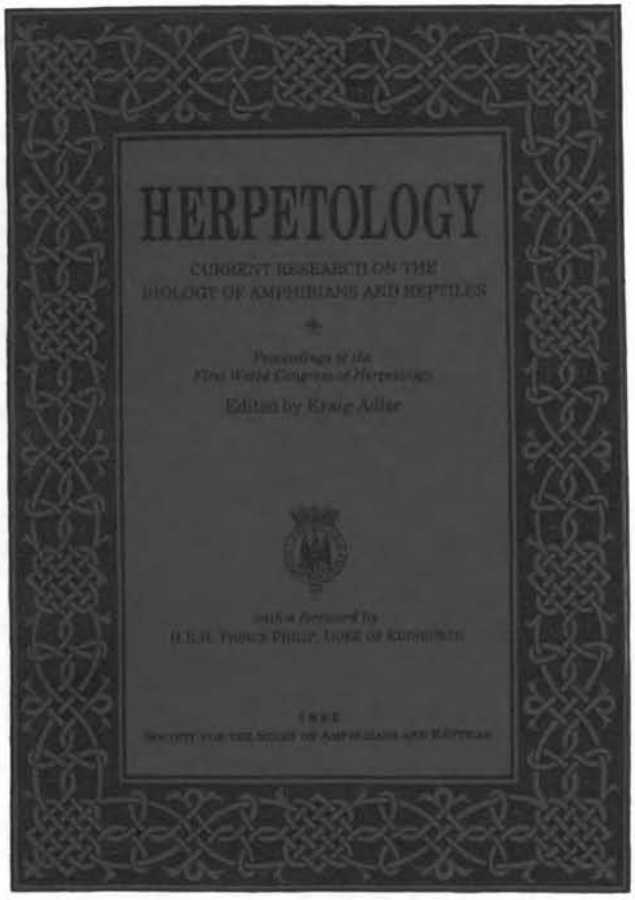
The nearly significant correlation suggests that visual searching skills may have some common ground between finding snakes and finding Waldo. The correlation explains slightly less than half of the total variance ($r^2 = 0.48$), and other important attributes of being a successful visual snake searcher (e.g., motivation, alertness under trying field conditions, etc.) must account for the majority of a person's snake searching skill. Nonetheless, it is worth noting that assignment of the person with the lowest Waldo score to some other duty would have increased the average sighting rate and improved the reliability of estimates of snake density.

During the execution of the Waldo tests I noted difficulties in self-timing. An independent timer will administer future tests. I hope this first attempt at predicting observer bias in visual searching tasks will inspire others to quantify interobserver variability and identify suitable measures for screening herpetological searchers.



Acknowledgments.—I wish to thank anonymous individuals who took the Waldo test and performed the numerous snake censuses. Steve Corn, Daryl Karns, Tom Fritts, and Bruce Bury suggested improvements to the manuscript. Funding for this work was provided by the U.S. Fish and Wildlife Service through the Arizona Cooperative Fish and Wildlife Research Unit and the National Ecology Research Center.

"HERPETOLOGY" VOLUME NOW AVAILABLE

THIS NEW BOOK CONTAINS THE UPDATED PLENARY lectures from the First World Congress of Herpetology. These chapters, by leading authorities on amphibians and reptiles, present a broad review of contemporary herpetology and are an excellent collection of readings for herpetology courses and graduate students. The book is extensively illustrated.

Viable Triploid Hybrids Between A Large Frog, *Rana catesbeiana*, And A Small One, *Rana septentrionalis*

The largest North American frog, the bullfrog (*Rana catesbeiana*), is related to one of the smallest, the mink frog (*Rana septentrionalis*). Hybrids between them, produced by artificial insemination in the laboratory, show characteristic syndromes and die before feeding (Elinson 1977, 1991; Kao and Elinson 1985). However, hybrids occasionally survive (Elinson 1977). I report here that viable hybrids are triploid and that they metamorphose at a larger size than do *Rana septentrionalis*.

When eggs from a *R. septentrionalis* female (Erin, Ontario) were fertilized with sperm from a *R. catesbeiana* male (Quebec), most of the embryos had very large heads (macrocephaly). A few appeared more normal, and six began feeding and growing. Chromosome preparations from corneas of four metamorphosed frogs showed that two were triploid (3N=39) and the other two were likely triploid (Fig. 1). Isozyme patterns for lactate (LDH) and isocitrate (IDH) dehydrogenase were run for these frogs, and the relative gene dosages indicated that all were triploids with a diploid set of *R. septentrionalis* chromosomes and a haploid set of *R. catesbeiana* chromosomes.

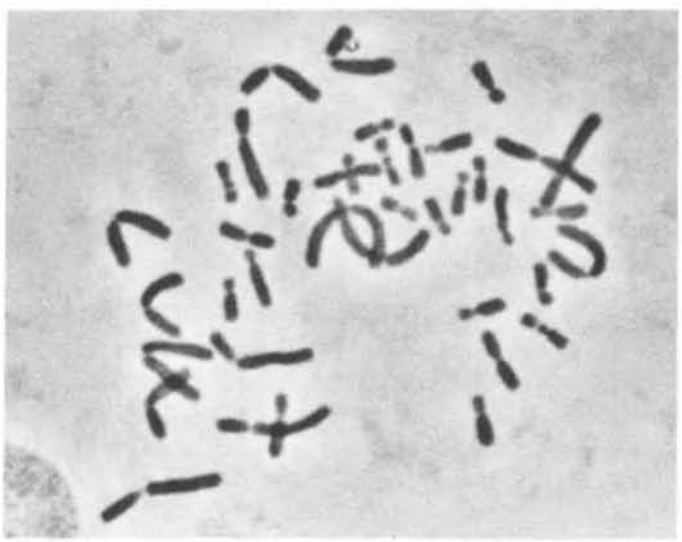

FIG. 1. Chromosome spread from a hybrid showing the triploid number (39) of chromosomes.

Triploids originate due to the occasional production of diploid eggs (Richards and Nace 1977; Wright et al. 1976), and the additional haploid set of maternal chromosomes permits hybrid viability (Bogart 1972; Elinson and Briedis 1981). Reexamination of isozyme patterns of viable hybrids, reported previously (Elinson 1977), suggests that they too were triploid (Fig. 2).

The addition of a haploid set of *R. catesbeiana* chromosomes in the hybrids appears to have increased the size at metamorphosis. Diploid *R. septentrionalis* and triploid hybrids were raised under similar conditions, although the *R. septentrionalis* tadpoles were kept at higher densities (2-3 times) for the first five months. Metamorphic climax, as indicated by forelimb emergence, occurred at 231 ± 39 days (N = 14) for *R. septentrionalis* and 249 ± 16 days (N = 5) for the hybrids. At completion of tail resorption, *R. septentrionalis* froglets were 3.0 ± 0.2 g and 2.3 ± 0.5 cm (N = 9), while hybrids were 3.7 ± 0.4 g and 5.2 ± 1.6 cm (N = 5).

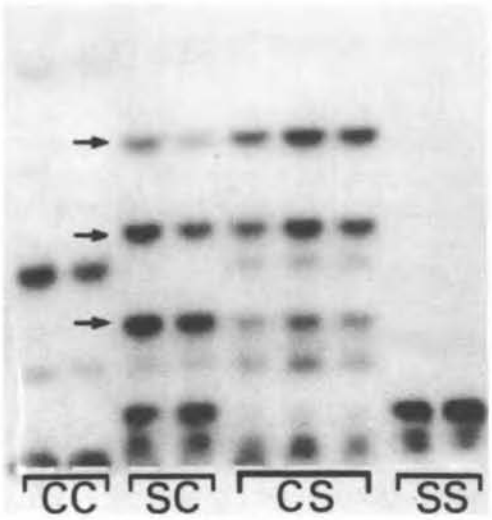

FIG. 2. Zymogram of lactate dehydrogenase (LDH). This gel shows LDH patterns for nine feeding tadpoles (19 days old) of the following types: *R. catesbeiana* ♀ x *R. catesbeiana* ♂ (CC); *R. septentrionalis* ♀ x *R. catesbeiana* ♂ (SC), *R. catesbeiana* ♀ x *R. septentrionalis* ♂ (CS), *R. septentrionalis* ♀ x *R. septentrionalis* ♂ (SS). Hybrid bands, consisting of subunits from both species, are indicated by arrows. Note that in SC tadpoles, the intensity of the hybrid bands is highest nearer the origin, while in CS tadpoles, the reverse is true. This skewing of the patterns is expected if the hybrid tadpoles contain a diploid set of chromosomes from their mother and a haploid set from their father. For instance, SC tadpoles would have a diploid set of *R. septentrionalis* chromosomes, and the pattern would be skewed towards *R. septentrionalis* (SS). The reverse is true for CS tadpoles.

Literature values for lengths of frogs at metamorphosis are 2.9–4.0 cm for *R. septentrionalis* and 4.3–5.9 cm for *R. catesbeiana* (Schueler 1975; Wright and Wright 1949). Our lab-raised *R. septentrionalis* were small compared to literature values, but the triploid hybrids fell in the range expected for *R. catesbeiana*. The larger size of the hybrids at metamorphosis could be due to better raising conditions, to triploidy, or to *R. catesbeiana* genetic contribution. A better controlled study would be required to sort out these factors, but it seems reasonable to hypothesize that *R. catesbeiana* genetic material can increase the metamorphic size of *R. septentrionalis*. These hybrids would be useful in investigating genetic control of growth and size in frogs.

Acknowledgments.—I thank Peter Pasceri for technical assistance and Marjorie Burnett (Laboratory of Analytical Systematics, Royal Ontario Museum, Toronto) for isozyme analysis. Supported by NSERC, Canada.

POINTS OF VIEW

The Need For Status Information On Common Herpetofaunal Species

The loss of biotic diversity is a matter of great concern to biologists and land management agencies. Much effort is directed at conserving individual species, and considerable thought has been directed at developing criteria for categorizing endangered and threatened species (e.g., Mace and Lande 1991). Much debate centers on rarity (Arita et al. 1990; Drury 1974; Kattan 1992; McCoy and Mushinsky 1992; Rabinowitz et al. 1986). Few authors have discussed commonness, however. Kattan (1992) placed it on the "wide – broad – large" end of Rabinowitz et al.'s (1986) geographic range – habitat specificity – local population size continuum. Out of eight categories using the Rabinowitz scale, only one reflects commonness (McCoy and Mushinsky 1992). However, a species could be perceived as common if it fell outside this category, such as a species that is widespread with a large local population size, but with restricted habitat specificity.

The Dilemma of Common Species.—In the United States, regulations generally do not address the management of habitats for wildlife and plants, except in specialized areas such as critical habitats for federally protected endangered and threatened species, parks, refuges, or wildlife management districts. Instead, management usually involves game or commercially important species, or species threatened with extinction. Consequently, relatively few species are the subject of direct population monitoring, and a high percentage of available time and effort is expended on those few species. With relatively small amounts of habitat protected and most funding directed at task-oriented research on a few species, the biological status of apparently common species may be overlooked.

A second problem is that biologists as well as the general public find it difficult to agree on what is a common species. Dictionaries (e.g., Webster's II New Riverside Dictionary, Berkeley Books, New York, 1984) use words such as "widespread," "familiar," and "occurring frequently" to define "common." Inasmuch as researchers know of species that are widespread but not common, are common but not familiar, and are not common but occur frequently, the meaning becomes somewhat ambiguous. A widespread and abundant species could suffer a 50% population decline, yet it still might be perceived as common to many people. We suggest that biologists should only use the word common to denote a species that can reasonably be expected to be observed or collected in its natural habitat, assuming that appropriate sampling techniques are used in appropriate habitats at appropriate times of the year. The word common may be used as a general observation of relative abundance but it should not be used in a conservation context unless a specific definition is provided.

A third problem involves perception and personal bias. Perceptions of commonness usually are based more on subjective personal experience than actual data. Inasmuch as habitats are changing rapidly and few biologists have experience with wide-ranging species throughout their ranges, the biological status of a species may change far more rapidly than our perceptions of its status. Biologists should not be too quick to suggest that a species is common and widespread without some basis other than subjective impressions or on data taken 20 years ago.

One result of biased or inaccurate perception is that there may be little attention devoted to the effect of various management practices on supposedly common species. Major changes in vegetation and faunal composition can occur as a result of management goals which do not favor common species. For example, landscapes with dense woody understories become more open with frequent prescribed fires. Eastern box turtles (*Terrapene carolina*) tend to occur in wooded environments. If fires are frequent, box turtle populations tend to decline and some populations might be extirpated. The risk of extirpation is especially high initially because first fires burn much hotter than subsequent fires. Thus, a manager with preconceived ideas of what are or are not common species may initiate management programs that actually lead to the inadvertent loss of a possibly declining species.

Is a Species Common? The Role of Museum Specimens.—Intuitively, it seems reasonable that in a region with a diverse scientific community, such as North America or more specifically, Florida, the commonness of an animal might be reflected by its representation in museum collections. As a result of our studies on box turtles (Franz et al. 1992), we decided to review national museum collections to determine the extent of recent box turtle collecting activity. Our examination helps to illustrate the problems of determining the present distribution, much less status, of a species lacking long-term population data, but generally perceived to be common.

We examined Florida box turtle records in all major U.S. museums (Appendix 1). We did not examine private collections or collections in schools or small regional museums. We recorded 842 specimens, of which 425 (50.5%) were deposited in the Florida Museum of Natural History (UF). Most non-UF specimens were collected prior to 1960 whereas UF collections peaked in the 1950's and 1970's (Fig. l). Most specimens resulted from the efforts of a few collectors in specific areas. For example, the large number of box turtle records at UF in the 1970's resulted largely from collections made by a single individual and are concentrated in only a few regions of the state.

We tabulated the year of collection within each county when data were available. For four counties (Hardee, Hendry, Martin, Union), we found no box turtle records. We divided the data into two categories, pre- and post-1970, and then calculated percentages within each category (Fig. 2). In 34 of 63 (54%) Florida counties with records, few box turtles (0-25%) were collected in the last 22 yrs. In 13 (21%) counties, between 26% and 49% of records occurred < 22 yrs ago whereas the majority of specimens were collected within the last 22 yrs in only 16 (25%) counties.

In most of the high percentage counties, few specimens were involved (Fig. 2). In addition, collecting biases are evident. For example, the large number of box turtles from Alachua County coincides with the presence of the University of Florida and an active herpetological community through the years; most of the large number of box turtles from Dade County were collected when Miami was a popular destination for northern tourists and prior to the intensive urbanization of 1960's. Thus, although the box turtle was common in museum collections, museum records give little reliable indication of the present distribution of box turtles in Florida.

In accounts in both the popular and scientific literature, the eastern box turtle (*T. carolina*) is a common species in eastern North America (Carr 1952; Conant and Collins 1991; Ernst and Barbour 1989; Pritchard 1979) and in Florida (Ashton and Ashton 1985; Moler 1988). A check of the Florida literature (Enge and Dodd 1992), however, reveals that virtually nothing on the biology of this turtle is available except for a few notes. The present status of Florida's "common" box turtle is unknown despite population declines elsewhere (Schwartz et al. 1984; Stickel 1978; Williams and Parker 1987), substantial international and domestic trade (New York Zoological Society 1991; Rea 1992) and extensive habitat destruction in Florida (Cerulean 1991).

What is Needed? Monitoring Protocols.—We suggest that many species perceived to be common, such as Florida's box turtles, may actually be declining. For example, populations of herpetological species once thought common, such as tortoises (*Gopherus agassizii, G. polyphemus*) and many frog species, or that are now generally perceived as common, such as the red-eared slider (*Trachemys scripta*) and snapping turtle (*Chelydra serpentina*), have declined in many areas. The disappearance of many frog populations offers a clear example of dramatic and unexpected declines over a short time period (Blaustein and Wake 1990; Livermore 1992; Wyman 1990). Rather than ignore common species until problems become glaringly apparent, a new approach is necessary.

The lack of historic population data makes it difficult to establish the causes of population declines, interpret them (Pechmann et al. 1991), or recommend management-related research. On the other hand, the long-term studies of once common species such as desert tortoises (Berry 1986) and many sea turtle populations (e.g., Bjorndal 1980) have allowed careful scrutiny of population trends (Crouse et al. 1987). With established monitoring programs begun in the 1970's, biologists were immediately aware of rapid declines and therefore in a better position to initiate conservation action, sometimes on an emergency basis.

In times of scarce economic resources, it is unrealistic to suggest that all species should be monitored, and we recognize that there are problems underlying the assumptions of using vertebrate indicator species to monitor population trends and habitat quality (Landres et al. 1988). The extirpation of or serious population declines in common species may not indicate the extent of impact on other species or identify the source of the problem. However, the decline or absence of common species in appropriate habitats gives an indication of questions that need to be addressed.

We suggest that biologists from academia, resource management agencies, and private conservation organizations need to develop monitoring protocols that include entire herpetofaunal communities and common species, in addition to species known to be in need of conservation management. Monitoring protocols should include site selection, identification of species and communities to be monitored and surveyed, and survey techniques. Species should be censused using standardized, quantified, population surveys (see Heyer et al. 1993 for example). Certain populations should be targeted for short-term monitoring, whereas other populations should be studied on a long-term basis (see Likens 1988). Effects of various management practices on common species also need to be considered.

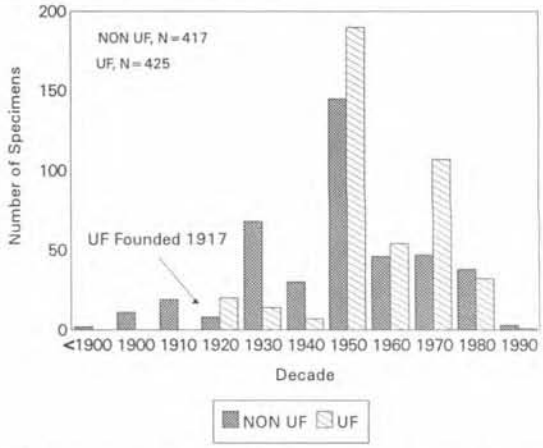

FIG. 1. The number of Florida specimens of the eastern box turtle in North American museum collections tabulated by decade of collection. UF = Florida Museum of Natural History.

FIG. 2. Florida specimens of the eastern box turtle in North American museum collections by county. A star = between 0-25% of the specimens were collected after 1970; circle = between 26-49% of the specimens were collected after 1970; square = > 50% of the specimens were collected after 1970.

As might be expected (although not expressly demonstrated), museum collections by themselves are unreliable to determine present status and distribution. Likewise, the use of technological innovations, such as GAP analysis (Scott et al. 1993), and regional databases such as those developed by the Natural Heritage Programs of The Nature Conservancy, must be used cautiously and are no substitute for field inventories. However, museum specimens record valuable information on historical distribution and other biological data. While we do not advocate unnecessary collecting, museum holdings need to be continuously augmented. Many governmental regulations require species inventory and

ecological assessment outside traditional academic research. During the course of such work, survey protocols should incorporate the collection of museum voucher specimens of even common species, especially in areas slated for destruction. In some cases, high quality photographic vouchers may serve as substitutes as long as photographs are deposited in museums with public access. All public lands should be surveyed for biological diversity. Finally, biologists should make the effort to preserve museum quality road kills, or animals that die from natural or other causes.

Acknowledgments.—Paul Moler, Florida Game and Fresh Water Fish Commission, generously supplied museum records used in this paper. We thank the museum curators for allowing access to their collections, and David Auth and James Layne for checking collection details. We thank John Eisenberg, Paul Moler, Richard Seigel, James D. Williams, and an anonymous reviewer for their comments on the manuscript.

Appendix I

Records for box turtles in Florida were examined from the following collections: American Museum of Natural History, Archbold Biological Station, Auburn University, California Academy of Sciences, Carnegie Museum, Cornell University, Field Museum of Natural History, Florida Museum of Natural History, George Mason University, Illinois Natural History Survey, Los Angeles County Museum, Louisiana State University,

Milwaukee Public Museum, Museum of Comparative Zoology, Museum of Vertebrate Zoology, National Museum of Natural History, North Carolina Museum of Science, Northeast Louisiana University, Ohio University, Southern Illinois University, Texas A&I University, Texas A&M University, Tulane University, University of Alabama, University of Central Florida, University of Colorado, University of Connecticut, University of Georgia Museum of Natural History, University of Illinois, University of Kansas, University of Kentucky, University of Michigan Museum of Zoology, University of South Florida, Yale-Peabody Museum.

A Consideration Of Iguanian Lizards And The Objectives Of Systematics: A Reply To Lazell

In the December, 1992, issue of this journal, Lazell (1992) commented on several issues of systematic philosophy and practice, as well as on the particulars of iguanian lizard taxonomy. Most of the general issues that Lazell addressed (e.g., "practical" utility versus scientific utility of classifications; paraphyly versus monophyly; overall similarity versus synapomorphy; definition versus diagnosis; taxonomy based on rankings of "key" characters versus taxonomy reflecting recovered evolutionary history) have all been resolved in the leading systematics journals (e.g., *Systematic Biology*), and, therefore, should not warrant further discussion here. However, Lazell's manuscript included a novel iguanian classification that represents a step backward for systematics, and because his manuscript survived peer review it must be that Lazell's viewpoint is shared by at least some proportion of the readership of *Herpetological Review*. It is for these reasons that we respond.

Systematic philosophy.—The signal difference between Lazell and leading systematists is in his rejection or misunderstanding of the fundamental importance of evolutionary history to systematics and of a set of logical techniques, collectively referred to as phylogenetic systematics or cladistics, that are used to estimate this history of evolution. The phylogenetic approach is predicated on the assumptions that (1) characteristics of ancestors are passed to their descendants in the same or modified form, and (2) the "nested" distribution of shared derived characters (synapomorphies) among taxa can be used to infer pattern of descent (Henning 1966). The most controversial aspect of cladistics for precladistic systematists is that phylogenetic (= cladistic) taxonomies report unambiguously the recovered patterns of evolutionary relationships among taxa.

The older paradigm of systematics (labelled, ironically, "evolutionary systematics"), here exemplified by Lazell's approach, is to employ overall similarity and "good" characters that meet some arbitrary criterion of taxonomic "utility," regardless of whether the groups recognized on this basis are logically consistent with evolutionary history. Further, in this approach some characters confer "family" rank on particular groups while others warrant only "subfamilial" or "generic" rank, regardless of the evolutionary relationships of the lineages under consideration. This approach is typical of systematics before the middle 1970's in that it represents a search for a hierarchy of kinds (=classes) of organisms that was then considered heuristic for the study of evolution. This approach was subsequently rejected by most systematists because they recognized that a *defined* hierarchy of kinds of organisms is logically unrelated to the evolutionary hierarchy and actually is detrimental to the study of evolutionary processes. More fundamentally, it was recognized that taxa (lineages and the historical groups that they can become) cannot be *defined* by rules because they are not sets in any rigorous (intensional) sense (Ghiselin 1981; Hull 1978, 1981; Wiley 1989). Because traditional, nonevolutionary classifications (those preferred by Lazell) make no distinction between invented abstractions (paraphyletic groups) and those entities that are discovered (monophyletic groups), they are anathema to scientific utility and inquiry. Alternatively, if classifications are based exclusively on the pattern of evolutionary history (that is, based on cladistic principles), we can use them to help study many things about historical processes, such as the evolution of behavior, life history, anatomy, physiology, and karyology, as well as historical biogeography. This lack of a firm evolutionary base in "evolutionary" systematics is the fundamental flaw that limits its scientific value (de Queiroz 1988) and which led many evolutionary bioloigsts to conclude that systematics was irrelevant to scientific inquiry. The larger issue, then, is not, as Lazell would have it, the efficiency of systematics as a button-sorting activity, but whether systematics is to be part of evolutioary biology. Most evolutionary biologists have already voted; it is no coincidence that the upsurge of interest in systematics comes as the same time that cladistics, a taxonomic approach with a firm philosophical base, has taken the stage.

Lazell's viewpoint is well illustrated by his discussion of the nature of higher taxa. He considers higher taxa to be "words, not organisms" that are "arbitrarily delimited by humans" but he still allows that they can "originate." Does he really mean to claim that sets, abstractions that extend from their definitions, can have histories? Could one talk about the unitary past and present of the set of "my car and three geese" or "reptiles excluding the closest living relatives of crocodilians and including the closest fossil relatives of mammals?" Further, although nonhistorical science, like physics and ecology, deals with classes of entities and their classes of interactions, historical science, as exemplified by systematics, generally deals with unitary entities (e.g., species and monophyletic taxa such as Mammalia and *Brachylophus*), their component parts, and their histories.

Paraphyletic groupings hinder science because they are neither scientifically useful classes, abstractions whose definitions (intensions) extend from hypotheses of natural regularities (like "herbivores" or "gold"), nor are they unitary or historical entities. As a more germane example, the historical entity that we call Iguania (iguanian lizards) would still exist if humans had failed to discover it. It is objectively real because it is the manifestation of what a single ancestral species has become through evolution, represented at this point in time by about 1000 living and uncounted numbers of fossil species. On the other hand, if a set is defined by Lazell such as "all iguanians that lack zygodactyl feet" (i.e., Lazell's concept of Iguanidae = former "Iguanidae" + former "Agamidae"), that set of species owes its "existence" not to historical descent or objective reality, but to Lazell's definition. Therefore, if Lazell decides in the future that his classification is no longer useful, the abstraction that he currently refers to as "Iguanidae" will disappear because, as an abstraction, it never really existed. Regardless of how Lazell constructs definitions in support of his paraphyletic classifications, some of his "iguanids" will continue to share a more recent common ancestor with chameleons than with other of his "iguanids." We cannot conceive of any overriding utility that could justify this misrepresentation of recovered evolutionary history.

Characters and character analysis.—With respect to our character analysis of iguanians, Lazell suggests that we reached erroneous conclusions in part because of our eschewing differential *a priori* character weighting and intuition based on perceptions of general similarity. He also faults us for not offering "proof" of our conclu-

sions. "Proof" is not within the realm of science (Popper 1968, 1979) so we must claim only that we have offered evidence for our conclusions. Lazell's view of what constitutes a "good" character is difficult to address because he is not interested in the phylogenetic information content of characters, only in their "utility" for button-sorting. Moreover, because his concept of character weighting has to do with ease of observation (based on his subjective opinion) rather than on the reliability of the character with respect to phylogenetic signal, his views are far removed from mainstream discussions of differential charcter weighting (e.g., Carpenter 1988; Farris 1969; Hecht and Edwards 1977; Wheeler 1986). Nevertheless, because most proponents of "evolutionary systematics" do not take Lazell's extreme position on classifications and characters, it is illustrative to see what several of Lazell's statements would mean in an evolutionary context.

Lazell mentions that a character that he would weight heavily is a derived aspect of tongue morphology, reticular papillae on the foretongue (Schwenk 1988), shared by anoles and chamaeleonids (*sensu* former "agamids" and chameleons). However, if this feature were taken as unassailable evidence of a chamaeleonid-anole grouping, this would not support the recognition of an "Iguanidae" (in his sense or the older one), because this feature would support the conclusion that anoles are more closely related to chamaeleonids than they are to such genera as *Polychrus* (which certainly shares a *gestalt* with anoles, as well as a number of derived characters — Frost and Etheridge 1989; Williams 1988). Lazell's discussion of other chamaeleonid characters is confused and misleading, with little regard for evaluating appropriate organismal life stages (= semaphoronts) or for alternative lines of evidence.

Lazell's assertion that acrodonty is an unacceptable basis on which to group "agamids" (i.e., chamaelonids without zygodactyl feet) and chameleons is untenable. This dentition character has been considered a "useful" (and phylogenetically informative) feature for 70 years (Camp 1923), and although some have suggested that acrodonty in iguanian lizards may have arisen convergently (e.g., Williams 1988), no one previous to Lazell has ever argued that the alternative conditions (pleurodonty and acrodonty) were part of an observable continuum. Even though we would not argue that it is impossible for the putative synapomorphies shared by agamines, leiolepidines, and chameleons to be evolutionarily convergent, Lazell's published comments make the characterization of this set of features appear much more difficult than it actually is. Although the dental condition in former agamids (= leiolepidines and agamines) and chameleons is almost universally referred to as "acrodont" (i.e., teeth attached to the top of the dentigerous bones) as opposed to "pleurodont" (i.e., teeth attached to the sides of the dentigerous bones), the character posited to carry phylogenetic information is that in chamaeleonids the lateral teeth cease to be replaced in adults and become fused to the underlying bone (= oligophyodonty - Edmund 1969). Lazell is correct that many "acrodont" iguanians actually have near-pleurodont or pleurodont tooth attachments. However, that Lazell has discovered some individual lizards that have anterior lateral teeth unfused to underlying bone means to us merely that he has looked at young individuals and, regardless, this certainly does not support his thesis of a pleurodont (non-oligophyodont)-acrodont (oligophyodont) continuum. That there is variation in the size, shape, and position of the teeth on dentigerous bones we do not dispute. However, this is irrelevant to this particular discussion. If dental condition is so variable, why have we never seen "pleurodont" iguanians (the former "Iguanidae") with "acrodont" (oligophyodont) fused dentition or adult "acrodont" iguanians in which dental fusion does not take place?

The broader issue of the necessity of gaps in transformational characterizations for phylogenetic analysis has been taken up by others (e.g., Stevens 1991) and although it is widely believed that cladistics depends on features of no variation, or at least with self-evident gaps separating characters, this is not true (Farris 1990). If evolution and ontogeny are real processes, it follows logically that many features (all of them, if we knew all of the intermediates) must be distinguished for analytical purposes by imposed *defined* distinctions. The issue therefore devolves not on the gaps, but on whether systematists idealize their data and how they characterize hypothesized transformations for analysis. In this regard we agree with Lazell that systematists should be careful not to make problems for themselves through careless character individuation, although we dispute his particulars. Regardless, we think that cladists who publish character descriptions and data matrices where they can be examined and discussed, are making more of a contribution to evolutionary biology than systematists who base taxonomies on personal opinion or on characters of idiosyncratic "rank" value rather than on the preponderance of evidence of evolutionary history.

With respect to the condition of maxillary contact behind the premaxilla, Rieppel (1984) has also noted variation, so Lazell may be correct that this feature is not particularly informative. We have not looked at all specimens available of the Chamaeleonidae (particularly those taxa patristically distant from the "basal" taxa as hypothesized by Moody (1980), Rieppel (1986), and Klaver and Böhme (1986)), and we appreciate that all characters vary (this being a corollary of taxa being real entities). Nevertheless, it remains to be seen, when this variation is included in an analysis, if contact is synapomorphic for the group.

Even if Lazell were correct that the characters of dentition and maxillary contact are not defensible as evidence, there are other lines of support for a monophyletic Chamaeleonidae (former "agamids" + chameleons); they share a mandibular anatomy that is unlike than in *any* other lizard, as well as unique features of tongue anatomy and function (Schwenk 1988; Schwenk and Bell 1988; Smith 1988). Further, if the immunological distances published by Joger (1991) are accepted as evidence of chamaeleonid monophyly, Lazell is left only with the observation of individual variation in some characters (which does not reject them as homologues) and the assertion that his paraphyletic taxonomy illustrates something that he thinks is important but cannot be placed within the context of evolutionary biology.

Along these lines, Lazell may not like the phylogenetic hypothesis (that is, the grouping) that extends from an assumption of homology of septa in the guts of iguanids, because these septa are intraspecifically variable (even though this hypothesis of homology is congruent with other lines of evidence), but he needs to present evidence that the occurrence of these structures is due to convergence rather than to common descent. Simply claiming that we (and Iverson 1980) may be wrong does not make Lazell right. Further, to make progress we must accept at least some level of variation in characters due to age, size, and sex, as well as that due to subsequent evolutionary changes, including reversal. If not, we must be prepared to exclude feathers as a bird synapomorphy solely because eggs lack them, reject hemipenes as a squamate synapomorphy because roughly 50% of the organisms in this clade (the females) lack them, and reject nasolabial grooves as a synapomorphy of plethodontid salamanders because these grooves vary in depth, shape, and development.

Iguanian taxonomy.—Although an extensive discussion of the history of iguanian systematics is beyond the scope of this paper,

a short review is useful. Since 1923 (Camp 1923), only four "family-level" iguanian taxonomies have been accepted by one or more workers[1]: (1) the three-family arrangement, based on subjective evaluations of similarity and "key" characters, that is most familiar to readers—Iguanidae (nonacrodont iguanians), Agamidae (non-chameleon acrodont iguanians), and Chamaeleonidae; (2) the four-family arrangement of Moody (1980, 1983), in which the three living acrodont groups were accorded the nomenclatural status of families, Uromastycidae[2] (=Leiolepididae), Chamaeleonidae, and Agamidae, with the pleurodont iguanians retained in the traditional "Iguanidae"; (3) the nine-family arrangement of Frost and Etheridge (1989), which is based explicitly on recovered evolutionary history; and (4) the arrangement of Lazell (1992), in which chameleons are placed in one family, Chamaeleonidae, and the remaining acrodont iguanians are placed with the pleurodont iguanians in another family, the Iguanidae, this arrangement, like #1, based on subjective notions of overall similarity and "key" innovations[3].

No one has yet provided evidence for a monophyletic Iguanidae in either Lazell's sense (#4) or the older one (#1, 2) (e.g., Böhme 1990; Etheridge and de Queiroz 1988; Frost and Etheridge 1989; Lazell 1992; Miles and Dunham 1992; Moody 1980, 1982; Pilustrelli and Moody 1991), although evidence has been produced that suggests that the former "Iguanidae" is paraphyletic (e.g., Frost and Etheridge 1989; Moody 1982; Schwenk 1988; Williams 1988). Therefore, retaining a taxonomy that suggests relationships on the basis of *no* evidence of monophyly (the older arrangement), in contrast to *some* evidence for the paraphyly of this "taxon" (although these lines of evidence may be in mutual disagreement), cannot be considered "conservative" in any scientific sense *(contra* Böhme 1990; Pilustrelli and Moody 1991; Miles and Dunham 1992).

Moody's (1980, 1983) classificatory novelties (alternative #2) were in the recognition of two monophyletic groups as families (Uromastycidae (=Leiolepidinae of Frost and Etheridge) and Agamidae (= Agaminea of Frost and Etheridge)), which had traditionally been included within the former Agamidae, and the recognition of the Madagascan oplurine "iguanids" as the Oplurinae; otherwise it is logically consistent with the iguanian classification of Camp (1923) as modified by Romer (1956). Subsequently, Borsuk-Bialynicka and Moody (1984) recognized a fossil taxon, Priscagaminae, which caused them to reconsider the Uromastycidae to be a subfamily of the Agamidae, in effect re-embracing the traditional "family-groups" nomenclature of Camp (1923). Estes et al. (1988) and Frost and Etheridge (1989) showed that the "Priscagaminae" were a paraphyletic assemblage and could not be included in the former Agamidae without rendering it paraphyletic with respect to the chameleons and leiolepidines. Further work has been unable to resolve unambiguously the reality of a group composed of agamines + leiolepidines (i.e., the traditional Agamidae), with some evidence pointing to this group being paraphyletic with respect to chameleons (Smith 1988), and some evidence pointing to it being monophyletic (Joger 1991).

In the case of Lazell's iguanian classification (#4), promoting a classification based on *gestalt* and "key" characters, particularly when it is contrary to a body of unambiguous counter evidence of evolutionary history, is inconsistent with scientific practice. Indeed, if there is any classificatory scheme of the Iguania that *embraces* paraphyly and places itself outside of evolutionary biology by ignoring evidence of evolutionary relationship, it is Lazell's. This leaves only one taxonomy of those proposed under the conventions of the International Code (Anon. 1985) that is consistent with rigorous evolutionary biology, which is our nine-family arrangement. Lazell's innuendo about the motivations of scientists aside, we would have preferred not to recognize nine iguanian families. But, the fact remains that this is a conclusion consistent with the evidence of evolutionary history, unlike the other arrangements.

With respect to Lazell's concept of "utility," we do not understand why the informal groups (e.g., sceloporines, anoloids, iguanines) that have served Lazell so well for so long (by his own admission) are not worthy of formal recognition (these groups being delimited originally by Etheridge 1959, 1964, 1966; Savage 1958; Etheridge *in* Paull et al. 1976; Etheridge and Williams 1985; and Etheridge and de Queiroz 1988; only further supported by Frost and Etheridge 1989). Guyer and Savage (1992) discussed the issue of formal versus informal classifications in the context of anole systematics. They noted that the scientific issue is not one of formality versus informality, but whether the taxonomy informs or misinforms about evolutionary relationships. We suggest that both Lazell's and the earlier gradistic classifications of iguanians misinform about recovered evolutionary relationships. We consider the nine major iguanian groups that we recognized as families to be "useful" because they are logically consistent with recovered evolutionary history. They could not have been discovered if they had not been identifiable and there is no evidence that these groups are particularly closely related. Moreover, although some authors (e.g., Schwenk 1988) have presented legitimate evidence that at least the polychrotids[4] might be nonmonophyletic, parsimony suggests that all of the groups that Lazell accepts informally and we recognize formally are all historical entities (i.e., monophyletic). The taxonomy that we proposed (Frost and Etheridge 1989), albeit relatively unresolved, promotes progress because it does not suggest relationships for which there is no supporting evidence, nor does it hide ignorance under the canard of "utility." Further, the unrooted trees on which our taxonomy rests exclude a large number of possible inter-group relationships from consideration. We question what scientific purpose a nonhistorical collection such as "Iguanidae" (in Lazell's sense or the older one) would serve. Is the "utility" of such a group that it makes it easier for us to misinform students, or possibly worse, misinform ourselves about the evolutionary history that we wish we knew? The lack of resolution among major iguanian groups is real, however. We would prefer to have achieved a more resolved taxonomy and we hope that evidence will be discovered that will resolve the current impasse. Progress will not happen, however, if workers abandon the attempt to recover evolutionary history, or limit the evaluation of scientific hypotheses to subjective opinion (e.g., "For me that is simply not good enough for even subfamilial separation." —Lazell 1992:109).

In summary, Lazell's taxonomic opinions have little to do with evolution specifically or science generally. If they did, they would have been taken up when the arguments about parsimony, overall similarity, and subjective character weighting were timely. Fortunately, those workers who prize stability over progress and button-sorting taxonomies over those based on recovered evolutionary history will find it difficult to overturn the progress made over the last 25 years.

[1]Another classificatory system which is logically consistent with recovered history, but outside of the conventions of the International Code of Zoological Nomenclature (Anon., 1985) has been suggested (de Queiroz and Gauthier 1990; Norell and de Queiroz 1990). We do not address this approach because this iguanian taxonomy has not been comprehensively presented and because the issue of abandoning the International Code is outside of the scope of this paper.

[2]The first modern published use of Uromastycidae was by Böhme (1982) who followed Moody's (1980) dissertation.

[3]Camp (1923) recognized a Section Rhiptoglossa (following Wiegmann [1834] and Cope [1900]) which included only the chameleons, with the former Agamidae and Iguanidae placed in an admittedly paraphyletic Section Iguania (= Pachyglossa of most earlier authors). The Rhiptoglossa was implicitly synonymized with the Iguania by Romer (1956). Camp's sections equate to Lazell's iguanian families.

[4]Böhme (1990) has noted that the correct formation of the family-group name must be Polychrotidae, rather than Polychridae.

TECHNIQUES

Field Evaluation Of Using Passive Integrated Transponder (PIT) Tags To Permanently Mark Lizards

Identifying individuals permanently is an important step in any long-term study of vertebrate populations. Techniques vary, however, and some methods may be better than others. Permanently marking lizards presents difficulties that may compromise study objectives. Ideally, the marking techniques should not affect survivorship or behavior of the animal, should be permanent, should allow for individual identification, should be usable on lizards of different sizes, should be easily read, and should not create undue stress or pain to the individual (Ferner 1979; Lewke and Stroud 1974; Ricker 1956). Avoiding undue stress or pain is often important when working with endangered species.

Lizards have been marked by painting numbers or letters on the dorsum, attaching colored tape to tails, attaching aluminum bands to thighs, and by clipping toes (Ferner 1979). All these techniques present problems for satisfying criteria necessary for long-term marking (Le Boulenge-Nguyen and Le Boulenge 1986; Stoddart 1970; Woodbury 1956). In addition, no estimates of tag loss have been made for these techniques.

The use of passive integrated transponder (PIT) tags alleviates many of the problems inherent with other methods (Camper and Dixon 1988). PIT tags are glass-encased electromagnetic coils and microchips implanted under the skin or in the body cavity. Each PIT tag is encoded with a unique alphanumeric code that is read by generating a low-frequency electromagnetic signal with an external reader; the signal energizes the transponder at close range (1–5 cm), which causes it to transmit its code back to the reader (Camper and Dixon 1988; Fagerstone and Johns 1987). PIT tags are passive units and expected longevity of the tags are 15–20 yrs.

Equipment consists of PIT tags, a modified 3-cc plastic syringe, 12-gauge stainless-steel needles, and a PIT-tag reader. The syringes we received from the supplier were large and impractical for field use. We modified a plastic 3-cc syringe by replacing the plastic plunger with a length of brass wire that serves as a mechanical plunger to push PIT tags out of the needle. Groups of needles were loaded with PIT tags and carried into the field. PIT tags were held in place inside the needles by coating tags with antiseptic ointment. The ointment also served as an antibacterial agent that was injected into the lizard along with the tag.

Since 1988, we have been studying a population of blunt-nosed leopard lizards (*Gambelia sila*) on the Elkhorn Plain, San Luis Obispo Co., California (Germano et al., ms. in review). The blunt-nosed leopard lizard is a state and federally listed endangered species. Although toe-clipping has been used by other researchers to permanently mark blunt-nosed leopard lizards (Montanucci 1965; Tollestrup 1982; Uptain et al., *in press*), it was believed that another method should be tried that would cause less misidentification of individuals due to natural marking, would not mutilate individuals, and that would allow assigned numbers to be more easily and accurately read. Here we report on the efficacy of marking lizards with PIT tags during a long-term field study.

In August 1989 we began PIT-tagging lizards, and over the course of four years we marked 581 blunt-nosed leopard lizards (Table 1). When a lizard was first encountered, it was weighed and

measured, sex was determined, and reproductive status and age class (young or adult) were recorded. Individuals also were marked with a numeral on their dorsum using a felt-tipped pen, and injected with a PIT tag.

The area in which tags were injected varied over the course of the study because of tag loss or destruction. In 1989 we injected lizards (N = 52) subcutaneously in the dorsum just anterior to the tail with the needle facing towards the head. We later found that the skin was too tight in this area and that the tags tended to break through the skin. In 1990 and 1991 for all lizards (N = 172), and in July 1992 for hatchling lizards (N = 81), we injected tags subcutaneously in a lateral fold of skin on the torso by inserting the needle at a point just posterior to the shoulder and sliding the needle into the fold (Fig. 1). We believed that tag loss would be reduced in this area. However, tag destruction under the skin in several adults in 1991 led us to inject adults intra-abdominally starting in April 1992. We also found that well-fed hatchling lizards in July 1992 had tight skin over all their body, and we began injecting hatchling lizards intra-abdominally in August 1992.

FIG. 1. Blunt-nosed leopard lizard that is being injected subcutaneously with a PIT tag using a modified 3-cc syringe and a 12-gauge needle.

The rate of loss or malfunction of PIT tags in blunt-nosed leopard lizards was 8.4% for first recaptures and 4.1% for all recaptures (Table 1). Twenty tags were lost in lizards and three tags malfunctioned during 3.5 years of tagging. Of the 20 tags that were lost, 17 lizards lost tags that were injected subcutaneously and three lizards lost tags injected abdominally. These individuals were known to have had tags because either they still had marker-pen numerals on their backs or a scar was evident at the point where the tag had been inserted. Based on scarring, tags lost subcutaneously either worked their way back out of the point of entry (N = 6) or the tag broke through the skin where the tag resided (N = 11). Ten of the 11 tags that broke through the skin occurred in hatchling lizards marked in July 1992. These lizards were injected subcutaneously along the lateral fold, but because of a high abundance of food in this month, the lizards were well fed and their skin was tight over all their body. This prompted us to begin injecting all lizards intra-abdominally.

Three PIT tags malfunctioned during the study; two tags were in adult males and one was in a hatchling male. All had been injected subcutaneously. In the adults, one tag cracked and the other tag was completely broken, and only small pieces of glass were found under the skin. Male blunt-nosed leopard lizards are territorial (Montanucci 1965; Tollestrup 1983) and are very aggressive towards each other, often biting each other's flanks (Montanucci 1965). Both broken tags in adults may have been damaged during male combat. We found that one of the males with a broken tag had scars on its head that were not evident before the tag was damaged. The inoperable tag in the hatchling was intact, but each end of the glass housing was cracked.

TABLE 1. Number of *Gambelia sila* PIT-tagged, number recaptured, and number of tags lost from August 1989 – November 1992.

Total Tagged	No. Lizards Recaptured At Least Once	Total Recaptures	% Tags Lost / Lizard	% Tags Lost / Recapture
581	273	558	8.4%	4.1%

We have not found estimates of tag loss in lizards for other types of tags, but the loss of PIT tags is higher than what is desirable. Twenty of the 23 losses were due to tags that were injected subcutaneously. Loss may be decreased by injecting the tag into the body cavity, although we still found some loss of tags. Injecting tags intra-abdominally could damage internal organs; however, this method of PIT-tag attachment has been used with several species of captive lizards (Camper and Dixon 1988) and with free-ranging Sacramento mountain salamanders (*Aneides hardii*) as small as 40 mm SVL (N. Scott, Jr., pers. comm.) without apparent ill effects. We also have injected PIT tags intra-abdominally into 10 adult blunt-nosed leopard lizards that are in captivity, and all appear normal. Beginning in August 1992, we started injecting PIT tags into the body cavity of hatchling blunt-nosed leopard lizards as small as 50 mm SVL.

Unlike other techniques for tagging lizards, the PIT tag method is expensive. PIT tag readers cost about $950.00 for the least expensive model. In addition, each tag costs from $4.75 to $6.00 depending on the quantity ordered. The price of readers and tags may decrease in the future as this system is used more widely.

Loss of information in population studies is due to lost tags or illegible marks. Errors in data for marked animals derive from errors in applying, reading, or recording codes. The PIT tag method overcomes some of these problems for marking lizards, but our field evaluation of tag loss in blunt-nosed leopard lizards suggests that tags must be placed inside the body to decrease the rate of tag loss.

Acknowledgments.—These studies were supported by funds from: California Department of Fish and Game, and Endangered Species Tax-checkoff Funds administered by Ronald Schlorff (1988-1991); The Nature Conservancy, administered by Richard Reiner (1989); and U.S. Bureau of Land Management, administered by Larry Saslaw (1989-1992). Susan D. Williams helped with various phases of the field work, and compiled, entered, and verified computer-based data, and assisted in editing and producing reports. Many people assisted in field work in the past four years, but special thanks are given to Walter Tordoff III, Larry Saslaw, and Vida, Damien, Rochelle, and Melanie Germano. John Brode, Jim Lidberg, Gail Kobetich, Richard Reiner, Larry Saslaw, Ron Schlorff, George Sheppard, and Charles Warner contributed logistic support in obtaining equipment, funding, and permits. We thank N. J. Scott, Jr. for reviewing an earlier draft of this paper.

HERPETOLOGICAL HUSBANDRY

Earthworms: A Balanced Diet For Small Snakes?

Earthworms are included in diets of many reptiles, including some small snakes that seem to prey upon them almost exclusively. In captivity, species of *Storeria, Diadophis, Thamnophis, Carphophis,* and *Virginia* have been maintained on diets comprised solely of earthworms for periods of up to several years. Yet there is little published evidence that earthworms represent a complete and balanced diet for these small snakes.

A complete diet as defined by nutritionists is one which will allow growth and reproduction of the species in question. The following observations on the captive breeding of *Virginia valeriae valeriae* suggest that commercially raised earthworms do represent a balanced diet for this species.

Two gravid female *V. valeriae* were captured in northern Virginia in July 1989. One female aborted 8 young in August 1989, and the other delivered 8 live young later that month. Worms were made available to the young snakes at all times, and no other food items were offered. Worms were obtained locally.

Three escapes, a death of unknown cause, and an accident reduced the number of young to three females, which reached an average total length of 21.6 cm by one year of age. We found no data regarding the size of wild *V. valeriae* at one year of age, but our data are comparable to those for wild *V. striatula* of the same age (Clark 1964). Details on the husbandry and breeding of *Virginia valeriae valeriae* are outlined in Rossi and Rossi (1992).

All three females copulated from 28 March to 6 April 1991 with a male collected in Florida. One female died in dystocia on 30 June 1991 with six dead, nearly full term embryos (N = 6, SVL = 63.6 mm, TL = 77 mm). The second female gave birth to five young (2 dead, 3 live) on 1 July and the third female gave birth to four young (1 dead, 3 live) on 2 July 1991. High natal mortality in captivity has been observed in a number of wild caught females of this species (pers. observ.; Morris and Walsh 1991).

Litter sizes were similar to those reported for wild populations of this species (Anderson 1965; Collins 1982; Dundee and Rossman 1989; Minton 1972; Smith 1961). At two years and two months of age, the two remaining females had reached an average total length of 25.0 cm. Conant and Collins (l991) report that 25 cm TL is typical for adult *V. valeriae*. These observations indicate that earthworms represent a complete diet for *V. valeriae*, and may be applied to captive maintenance and breeding programs of other small, worm-eating reptiles.

Acknowledgments.—We thank Lyndon Mitchell for his helpful comments on the manuscript.

LIFE HISTORY NOTES

Instructions for contributors to Life History Notes appear in volume 24, number 1.

ANURA

BUFO BOREAS (Boreal Toad). **PREDATION.** The distribution and abundance of *Bufo boreas* in Colorado has declined considerably in the last 20 yrs (Corn et al. 1989. U. S. Fish and Wildl. Serv. Biol. Rep. 80(40.26), 56 pp; Carey, *in press*. Conserv. Biol.). Predation, although a natural occurrence that is unlikely to have caused this decline, may be a serious threat to some remaining populations of *B. boreas*. On 13 May 1992, between 1230 and 1430 h, I observed six dead adult *Bufo boreas* at a glacial pothole pond in Rocky Mountain National Park, Larimer County, Colorado, USA (Kettle Tarn, Lat 40° 30' N, Lon 105° 31' 48" W, elevation 2810 m). Most of these were partial carcasses found amongst hummocks of dried sedges (*Carex*) along the shore. In two cases, I found the head of a toad with the dorsal skin and hind legs attached. A pair of ovaries, full of mature ova, was within 50 cm of one of these carcasses (Fig. 1). Three other carcasses consisted only of pairs of ripe ovaries. The sixth dead toad was a large female (SVL = 92 mm), found intact under water at a depth of 50 cm. Breeding had begun at this site (I observed at least 11 recent egg masses), but I found only one live toad during this visit. This may have been because cool temperatures (air 9°C), intermittent thundershowers, and strong winds reduced activity by toads.

The partial carcasses of *B. boreas* indicate a vertebrate predator. Olson (1989. Copeia 1989:391-397) observed ravens (*Corvus corax*) eating *B. boreas* at breeding aggregations in Oregon. Her description of carcasses (head, dorsal skin, limbs, and eggs from gravid females) was similar to toad remains at Kettle Tarn. Raccoons (*Procyon lotor*) and possibly striped skunks (*Mephitis mephitis*) also prey on toads by eviscerating them (Groves 1980. Amer. Midl. Nat. 103:202-203; Schaaf and Garton 1970. Herpetologica 26:334-335). Both *P. lotor* and *M. mephitis*, however, are rare at high elevations in Colorado, except near human developments (Armstrong 1972. Univ. Kansas Mus. Nat. Hist. Monogr. 3:1-415). Because of the nature of the carcasses, the probable lack of mammalian predators, and the presence of *C. corax* (I observed a raven flying overhead carrying an object in its beak when I arrived at the pond), the identity of the predator at Kettle Tarn is likely *C. corax*.

Predation may occur at high rates in some breeding aggregations of *Bufo*. Olson (op. cit.) observed > 60% mortality (59 individuals) of *B. boreas* in two days at one of her three Oregon sites, Groves (op. cit.) found 46 partially eaten *B. americanus* in one small pond in Maryland, and Schaaf and Garton (op. cit.) found about 50 dead *B. americanus* at a pond in Illinois. The predation rate on breeding females at Kettle Tarn may have been >20%. At least 18 egg masses were deposited at this site in 1992, and at least 5 of the dead toads found 13 May were females; therefore, the minimum mortality estimate was 22% (5 of 23) in one instance. The population of *B. boreas* at Kettle Tarn is one of the largest remaining in the southern Rocky Mountains (pers. observ.), so high mortality, even to a "natural" cause, is a serious concern.

Funding for studies in Rocky Mountain National Park was provided by the National Park Service through an interagency agreement. I thank Mike Jennings and Joe Kiesecker for additional observations at Kettle Tarn, and Mike Jennings, John Ramsey, Bruce Bury, and Deanna Olson for comments on the manuscript.

CROCODYLIDAE

ALLIGATOR MISSISSIPPIENSIS (American Alligator). **DIET.** On 15 June 1988, I found an 8.75 cm long *Dasyatis americanus* (Atlantic southern stingray) tail spine embedded in the heavy dorsal muscle behind the alligator's jaw hinge of an adult male, 3.14 m long, *A. mississippiensis*. The spine could have been embedded by the large stingray flipping its tail upwards over the alligator's head and driving it downwards to the alligator's neck when the ray was grabbed by its body or wing. The alligator was captured in tidal marshes on the eastern side of St. Catherines Island, Liberty Co., Georgia. This size spine corresponds to a >1.0 m wide *D. americanus* (John Crawford, UGA Marine Extension Service Skidaway Island, Georgia 31411, pers. comm.). On 24 June 1990, a second *D. americanus* spine, 4.8 cm long, was found protruding from the tongue of a 1.58 m female *A. mississippiensis*. The spine was driven into the buccal aspect of the tongue and protruded out the ventral skin surface. The defensive strike probably occurred while the smaller stingray was being bolted and swallowed. The positions of both of these spines strongly suggest that the alligators had been struck by the stingrays in retaliation to being seized by the predator. Both spines were found without sheathing suggesting they had been embedded for some time. The alligators appeared to be of normal weight and in good health. No signs of infection about the spine were evident.

Feeding habits of alligators vary according to size class, habitat selection, and prey availability and suitability (Chabreck 1972. Proc. Ann. Southeast. Asoc. Game and Fish Comm. 25:117-124.). Blue crabs (*Callinectes sapidus*) and horseshoe crabs (*Limulus polyphemus*) are common in St. Catherines Islands' tidal waters. *A. mississippiensis* which rake their jaws through the mud and sand of the saltmarshes while foraging for blue crabs (Tamarack 1989. Proc. 8th Meeting IUCN Crocodile Specialist Group, Quito, Ecuador 86:105-118) undoubtedly encounter rays.

Submitted by **JAMES L TAMARACK**, New York Zoological Society's Wildlife Survival Center, St. Catherines Island, Route 1, Box 207-Z, Midway, Georgia 31320, USA.

ALLIGATOR MISSISSIPPIENSIS. (American Alligator). **NEST MATERIAL.** The optimal incubation temperature for an alligator is 31.7°C with a range of 29.4°C to 32.8°C. Incubation temperatures above 33.9°C cause hatching success to fall off rapidly (Joanen et al. 1987, *In* G. J. W. Webb, S. C. Manolis, P. J. Whitehead (eds.), Wildlife Management: Crocodiles and Alligators, pp. 533-537. Surrey Beatty and Sons, Sidney, Australia.). Decaying vegetation in crocodilian nests may insulate the nest from extreme heat as well as produce heat (Magnusson et al. 1989, *In* C. A. Ross (ed.), Crocodiles and Alligators, pp. 118-135. Facts on File, New York.). Organic material in the nest of the American alligator contributes to microbial degradation of the egg shell, facilitating hatching (Ferguson 1981. Science 214:1135-1137; Ferguson 1981. Experientia 37:252-254).

On 23 June 1991 we observed an unusual alligator nest on a sanitary landfill, Recovery One, Inc., New Orleans, Orleans Parish, Louisiana. The nest (ca. 2 m diam x 0.8 m high) was composed almost entirely of layers of various plastic bags (Fig. 1). A few curious items included a flip-flop sandal, a 10 cm high plastic baby doll, and a yellow plastic vegetable oil container. Less than 5% of the nest material was organic. A 2-m (total length) female guarded the nest closely. The temperature in the egg chamber was 36.7°C on 13 August 1991 at 1800 h. On 1 September 1991, we excavated the nest and found a clutch of 36 eggs. Most embryos died early during development, or the eggs were infertile. Seven developed embryos measured approximately 5 cm, 8 cm, 9 cm, and 22 cm (N = 4). The four largest embryos were in the final stages of development.

On 5 July 1992 a second nest was found 4.6 m from the 1991 nest. The egg chamber temperature was 35.0°C at 1800 h. This clutch consisted of 39 eggs, none of which hatched. All of the eggs died in the early stages of development. We attribute the high incubation temperatures to the lack of organic material in the nests. It is not known whether there would be enough microbial degradation in either of these garbage nests to facilitate hatching.

We thank Robert A. Thomas for reviewing the manuscript.

LACERTILIA

ANOLIS CAROLINENSIS (Green Anole). **SOCIAL PATHOLOGY.** On 15 August 1992, while conducting a behavioral study of *Anolis carolinensis* along the Augusta Canal, 3 km west of Augusta, Richmond County, Georgia, we observed a pathological social interaction which had three functional parts that were sequenced as follows.

At 1632 h a small adult male *A. carolinensis* (SVL 50 mm) ran down a 1.2 m high concrete wall in pursuit of a smaller conspecific male (SVL 42 mm). The 50 mm male grabbed the 42 mm male by the nape of the neck in a typical pre-copulatory hold and attempted to copulate. The 42 mm male struggled and escaped, but was chased and secured with another neck hold. Again the larger lizard attempted to copulate. The smaller lizard countered with vigorous struggling, while extending his dewlap. Twice the smaller male briefly escaped and was recaptured by the larger male. During this time (13 min) the males had moved from the wall to the ground.

At 1645 h the larger male shifted his nuchal hold to a deep mouth grip on the side of the smaller male's throat. The larger animal violently shook the smaller male in short repeated bursts and periodically slammed the smaller male's head on the ground. As the smaller male's attempts to escape became more feeble, the larger male moved his grip, using quick full-mouth bites, to the smaller male's head. At 1655 h the smaller male appeared dead.

At 1656 h the larger male attempted to swallow the corpse head-first, but was able to only partially engulf the head. By 1705 h the larger lizard had dragged his victim up the 1.2 m wall. While maintaining a head hold, the 50 mm male straddled the 42 mm corpse and walked toward a clump of vegetation on the backside of the wall. Before they disappeared into the underbrush, we attempted to noose the subjects, resulting in both being dropped to the ground. Although the male attempted to flee, he did not release the dead male's head, not when he was subsequently noosed, nor when he was transferred to a plastic bag.

Social contact between conspecific anoles has three general intents: (1) courting and copulation; (2) contesting over territorial rights; and (3) possibly cannibalism (Mitchell 1986. Soc. Study Amphib. Rept. Herpetol. Circ. 15:1-37). The behavior in the above narrative contains obvious perversions of all three intents: (1) the copulatory attempt was homosexual; (2) the aggression went beyond the displacement of a rival and ended in death; and (3) the cannibalistic response was made to a conspecific too large to eat (Fig. 1).

We offer two interpretations of the perpetrator's behavior. It was: (1) a dysfunctional response by a sexual-aggressive deviant, perhaps suffering from a physiological pathology, or (2) a representative propensity for behavioral extremes by a particular age-sex class. Should the latter be true, there may be demographic repercussions. On the study area in August and September, the low weedy vegetation, a microhabitat not usually frequented by territorial males, teemed with hatchlings and small juveniles, as well as occasional small adult males. If small adult males are prone to aggressive/cannibalistic behavior (e.g., Jenssen et al. 1989. Anim. Behav. 38:1054-1061), then the reward would be an immediate meal and (if a male were eaten), fewer competitors the following spring.

These observations were made possible by a faculty participation grant to TAJ as a contract (DE-AC09-76SR00-819) between the United States Department of Energy and the University of Georgia's Savannah River Ecology Lab.

Submitted by **THOMAS A. JENSSEN,** Biology Department, Virginia Tech, Blacksburg, Virginia 24061, USA, and **KATHERYN A. HOVDE,** Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA.

ANOLIS CHLOROCYANUS (Hispaniolan Green Anole). **AQUATIC ACTIVITY.** At least three species of *Anolis* are known to engage in aquatic activity, including feeding behavior (Mattison 1989. Lizards of the World. Facts on File, New York, 192 pp.). Schwartz and Henderson (1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville. xvi + 720 pp.), however, documented no such tendencies among West Indian anoles. On three separate occasions at two different locations in the Dominican Republic we have observed *Anolis chlorocyanus* utilizing water as a refuge. In January 1986 and March 1988 along the edge of a spring-fed pool near Neiba, Baoruco Province, we noted 10-15 subadults and adult females, but no adult males at either time, on emergent vegetation. When approached, these lizards quickly jumped into the water. Many would swim along the surface to vegetation farther from shore, but others dove into the water and often remained beneath the surface, clinging to submerged vegetation for periods of time up to at least 1.5 min. No evidence of aquatic foraging was observed, although numerous insects were found on the vegetation and aquatic arthropods were common among the submerged portions of plants. Swimming consisted of lateral undulations of the body and tail with tightly adpressed limbs. In June 1991 along a spring-fed irrigation system near Boca de Cachon, Independencia Province, we observed a single subadult dive from a shoreline rock into the water. We never saw the lizard surface in spite of intensive efforts to locate it again. It may have drifted a considerable distance with the current or emerged among nearby dense aquatic vegetation. At both sites, *A. chlorocyanus* was commonly encountered in non-aquatic habitats, implying that the use of water as a refuge is a facultative phenomenon.

Submitted by **ROBERT POWELL** and **JOHN S. PARMERLEE, JR.,** Department of Natural Sciences, Avila College, Kansas City, Missouri 64145, USA.

CARLIA BICARINATA (Bicarinate Four-fingered Skink). **PARTIAL ALBINISM.** An albino juvenile *Carlia bicarinata* was collected at 1400 h on 26 May 1986 from a savannah path 2 km E of Wipim Village in the southern Trans-Fly region of Western Province, Papua New Guinea. This species is normally a golden brown lizard with a broad dark lateral stripe, bordered by two narrower longitudinal stripes of yellow or cream, running from the snout, through the eye, and onto the tail. The albino juvenile was almost grey-green anteriorly fading to white posteriorly and on the tail. The dark lateral stripe, though still present, was much less evident between the lighter stripes. The eyes were not pink. Particularly conspicuous due to the light coloration of the skink, was a collection of ectoparasitic red mites in the axial pits of the forelimbs. This specimen will be deposited in the collection of the Natural History Museum, London (BMNH).

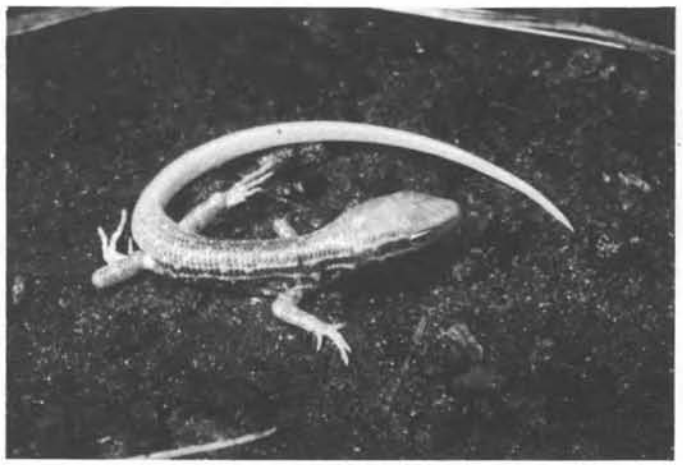

FIG. 1. Partial albino juvenile *Carlia bicarinata*, Western Province, Papua New Guinea.

Submitted by **MARK T. O'SHEA,** 46 Buckingham Road, Penn, Wolverhampton, WV4 STJ, England.

SERPENTES

AGKISTRODON PISCIVORUS CONANTI (Florida Cottonmouth). **PREY.** On 10 September 1992 at 2100 h, I collected a Florida cottonmouth (SVL 92.5 cm; TL 18.5 cm; wet mass 837 g) immediately after it had been hit by a vehicle on Hwy 71, 1.3 mi N of Blountstown, Calhoun County, Florida. The following day I palpated the snake carcass and extracted a partially digested *Ophisaurus ventralis* (SVL 22.2 cm; TL 60.7 cm; wet mass 76 g). The carcass of the eastern glass lizard was in three pieces: the body and anterior 1/4 of the tail, and the remainder of the tail in two pieces. It is not known whether the snake consumed the glass lizard whole, or whether it had swallowed an autotomized tail after consuming the body.

In their review of the diet of all three subspecies of *Agkistrodon piscivorus*, Gloyd and Conant (1990. Snakes of the *Agkistrodon*

BRITISH
HERPETOLOGICAL
SOCIETY

One of the oldest and largest herpetological societies in the world, *The British Herpetological Society* caters for all those interested in research, conservation, captive-breeding and educational aspects of the subject.

Membership benefits include:

* *The Herpetological Journal* - published quarterly, the journal publishes original research in herpetology from all over the world and has an international editorial board.
* *British Herpetological Society Bulletin* - published quarterly, contains news, views, and general articles on all aspects of herpetology.
* *Free information leaflets* - produced regularly on various aspects of conservation and captive breeding.
* *The Young Herpetologist's Newsletter* - the junior section's own publication with articles, news and quizzes.
* *Meetings* - about eight are held each year covering all areas of the society's activities.

Subscription rates for 1993:

Ordinary Membership (receive Bulletin)	£20.00
Full Membership (receive Bulletin plus Journal)	£25.00
Ordinary Family Membership	£30.00
Full Family Membership	£37.50
Full Student Membership (full-time education only)	£18.00
Young Herpetologist's Club (9-17 yrs):	
Basic Membership £5; *Bulletin Membership*, £10; *Group Membership*	£5/£10

THE KANSAS HERPETOLOGICAL SOCIETY
ANNOUNCES A
NEW LIMITED EDITION PUBLICATION

The Lizards of Kansas
by Edward Harrison Taylor

Kansas Herpetological Society Special Publication Number 2

The Kansas Herpetological Society announces the publication of a new Edward H.Taylor limited edition volume. Entitled ***The Lizards of Kansas***, this volume is the Masters thesis that Dr. Taylor submitted to the University of Kansas in 1916 upon his return from the Philippines. ***The Lizards of Kansas*** also contains two illuminating forewords by Hobart M. Smith and Joseph T. Collins. These two forewords greatly enhance the value of this new publication and reveal hitherto unknown facets of Taylor's professional development.

This publication is Taylor's first since his death in 1978 and will likely be the last by him. As this is a *one-time only* printing (only 400 copies), the value of the publication will only increase. All students of Taylor will surely want to add this publication to their libraries and others will find it provides a fascinating glimpse into Taylor's early background. This softbound volume with illustrations is available for only $10.00 postpaid; Kansas residents add 4.5% sales tax. Send orders to Karen Toepfer, KHS Secretary/Treasurer, 303 West 39th Street, Hays, Kansas 67601, USA. Please send checks or money orders only made out to "Kansas Herpetological Society." Allow 4-6 weeks for delivery.

Complex. SSAR, Oxford, Ohio) found reports of cottonmouths consuming four species of lizards: *Anolis carolinensis, Eumeces inexpectatus, Eumeces laticeps*, and *Scincella lateralis*. Although the eastern glass lizard is commonly eaten by other North American snakes (e.g., *Micrurus fulvius*; Jackson and Franz 1981. Herpetologica 37:213-228), I believe this is the first report of its consumption by a cottonmouth.

I thank Dale R. Jackson for commenting on the manuscript and for alerting me to the coral snake paper.

Submitted by **JOHN G. PALIS,** Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA.

HETERODON PLATIRHINOS (Eastern Hognose Snake). **DIET.** *Heterodon plahrhinos* feeds primarily on toads and other amphibians, but also has been reported to consume reptiles, insects, fish, birds, mammals, earthworms, isopods, centipedes, spiders, and snails (Ernst and Barbour 1989. Snakes of Eastern North America. George Mason Univ. Press, Fairfax, Virginia, 282 pp.).

On 7 July 1992, we captured a melanistic *Heterodon platirhinos* (65 cm SVL) crossing a gravel road ca. 0.4 km N of Flamingo Bay on the Savannah River Site, Aiken Co., South Carolina (for location, see Gibbons and Semlitsch 1991. Guide to the Reptiles and Amphibians of the Savannah River Site. Univ. of Georgia Press, Athens, 131 pp.). While performing its death-feigning behavior it regurgitated a millipede (Xystodesmidae: *Sigmoria laticurvosa*) and a beetle (Scarabaeidae: *Phyllophaga aemula*). Both of these animals are abundant in this area. This appears to be the first record of an eastern hognose snake consuming a millipede. Because there was no evidence of a *Bufo* sp. in the regurgitated material, we do not believe that the millepede was secondarily ingested. Several authors report beetles or insects in the diet (Edgren 1955. Herpetologica 11:105-117; Wright and Wright 1957. Handbook of Snakes of the United States and Canada, Vol. I. Cornell University Press, Ithaca, New York, 564 pp.). In addition, Hamilton and Pollack (1956. Ecology 37:519-526) report a centipede in the diet of *H. platirhinos*.

We thank Richard L. Hoffman for identifying the millipede and beetle, and J. Whitfield Gibbons and Chris J. Hudson for reviewing the manuscript. This work was supported by contract DE-AC09-76SR00-819 between the U.S. Department of Energy and the University of Georgia's Savannah River Ecology Laboratory.

Submitted by **MARK S. MILLS** and **S. REBECCA YEOMANS,** Department of Zoology, University of Georgia, Athens, Georgia 30602, USA, and Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA.

LAMPROPELTIS GETULUS (Eastern Kingsnake). **PREDATION FATALITY.** On 26 September 1991, on Saint Catherines Island, Liberty County, Georgia, we discovered a dead 1.55 m (TL) *Lampropeltis getulus* along the margin of a dirt road through sandhill habitat. The snake's head and neck were firmly held underground in a 3.5 cm wide burrow. Removal of the snake from the burrow was difficult. There was a palpable mass in the neck, and an elliptical turtle egg was removed through the snake's mouth. The egg was intact though it broke during removal. There were nine more intact eggs in the nest cavity and three broken eggs were retrieved from the snake's stomach. Six undamaged eggs (length 3.5–3.8 cm) were artificially incubated but failed to develop.

Knight and Loraine (1986. Brimleyana 12:1-4) suggest that *L. getulus* may search out and consume the contents of multiple turtle nests. We could not identify the eggs to species but the nest and eggs were consistent with either of two resident emydid turtles on St. Catherines Island, *Trachemys scripta* or *Deirochelys reticularia*. Apparently the snake swallowed the fourth egg inside the chamber and was unable to back out of the root-obstructed entrance hole. The egg failed to break and the snake struggled until it died from asphyxiation.

Submitted by **JAMES L. TAMARACK**, New York Zoological Society's Wildlife Survival Center, St. Catherines Island, Route 1 Box 207-Z, Midway, Georgia 31320, USA, and **BRIAN DOHERTY**, 1925 Nth 75 Ct., Elmwood Park, Illinois 60635, USA.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19:1–41), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 1985(3):802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. All specimen identifications *must* be verified by another authority (not one of the authors). Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to the Section Co-editors, Joseph T. Collins (USA & Canadian records only), Museum of Natural History—Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA, or Darrel Frost (the rest of the world), American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024, USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Phillips, C. A. 1991. Geographic Distribution. *Ambystoma maculatum*. Herpetol. Rev. 22:133.

CAUDATA

AMBYSTOMA MACULATUM (Spotted Salamander). USA: ILLINOIS: Fayette Co: 4 km W Rt. 128 on 3050N & 0.5 km S (39° 10'41"N, 88°51'31"W). 25 May 1992. J. E. Petzing. Verified By R. A. Brandon. Southern Illinois University at Carbondale (H–4110). County record; habitat is oak-hickory forest bordered by fields on N, E, & W.

Submitted by **ALLAN K. WILSON**, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA.

AMBYSTOMA OPACUM (Marbled Salamander). USA: MISSOURI: Montgomery Co: Danville Wildlife Area, ca. 3 km SSE Danville. SW 1/4, SE 1/4, NE 1/4, Sec. 6, T47N, R5W. 9 September 1992. Brian S. and Kellie Jayne Edmond. University of Missouri, Columbia (UMC 2107C). Verified by D. E. Metter. Active on land near pond at campground at night; new county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

AMBYSTOMA OPACUM (Marbled Salamander). USA: OHIO: Hamilton Co: Crosby Twp: Sec. 1, Paddy's Run Road, 400 m S Hamilton County border. 13 September 1992. Christopher T. McCarty, Anthony McCarty, and Jeffrey G. Davis. Verified by John W. Ferner. Cincinnati Museum of Natural History (CMNH 3641 and 3642). Pfingsten and Downs (1989, Salamanders of Ohio. Ohio Biol. Surv. Bull. New Ser. Vol. 7 (2): xx + 315 pp. + 29 pls.) show this species as occurring in the county based on a literature record, but did not indicate a voucher; new county record.

Submitted by **JEFFREY G. DAVIS**, Department of Herpetology, Cincinnati Museum of Natural History, Frederick and Amey Geier Research and Collections Center, 1720 Gilbert Avenue, Cincinnati, Ohio 45202, USA, and **CHRISTOPHER T. McCARTY**, 1121 Brough Avenue, Hamilton, Ohio 45015, USA.

AMBYSTOMA TIGRINUM (Tiger Salamander). USA: IDAHO: Owyhee Co: Sec. 7, T3S, R5W. 4 October 1990. Mark Vinson. Verified by Chuck Peterson. Idaho Mus. Nat. Hist. (IMNH 498). County record and significant range extension (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest, Univ. Press Idaho, Moscow, 332 pp.; Stebbins 1985, A Field Guide to Western Reptiles and Amphibians, Houghton Mifflin Co., Boston, Massachusetts, 336 pp.).

Submitted by **MARK VINSON**, USDI, Bureau of Land Management Aquatic Ecosystem Laboratory, Fish and Wildlife Department, Utah State University, Logan, Utah 84322–5210, USA.

AMBYSTOMA TIGRINUM (Tiger Salamander) USA: MISSOURI: Johnson Co: Warrensburg. April 1961. Paul Anderson. Verified by Joseph T. Collins (KU 89195). New county record within a hiatus in the range in western Missouri and eastern Kansas as shown by Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.) and extends the range ca. 30 mi SE of nearest known locality in Jackson County, Missouri (Johnson 1987, Amphibians and Reptiles of Missouri. Missouri Dept. of Conservation, Jefferson City, 368 pp.).

Submitted by **KEVIN R. TOAL**, Museum of Natural History, University of Kansas, Lawrence, Kansas 66045–2454, USA.

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). USA: NORTH CAROLINA: Moore Co: 4.2 km S Foxfire Village & 6.3 km SSE Foxfire Village. 21 November 1992. J. C. Beane and S. L. Alford. Verified by A. L. Braswell. North Carolina State Museum of Natural Sciences (NCSM photos JCB 92–2545 and JCB 92–2546). Two adult males taken AOR; photographed and released due to threatened status in state. New county record. Brimley (1907. J. Elisha Mitchell Sci. Soc. 23:150–156) recorded this species from Moore County, but that locality is now a part of Lee County. A. t. tigrinum has now been recorded from eleven counties in North Carolina, many of those represented only by old literature or "sight" records. In recent years, the species has been documented from six counties; only four of those have confirmed breeding sites (NCSM files).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611, USA, and **STANLEY L. ALFORD**, North Carolina Zoological Park, Route 4, Box 83, Asheboro, North Carolina 27203, USA.

EURYCEA LONGICAUDA GUTTOLINEATA (Three-lined Salamander). USA: NORTH CAROLINA: Richmond Co: 11.3 km WSW Ellerbe. 21 November 1992. J. C. Beane and S. L. Alford. Verified by A. L. Braswell. North Carolina State Museum of Natural Sciences (NCSM 31992). Adult taken AOR. New county record (NCSM files).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611, USA, and **STANLEY L. ALFORD**, North Carolina Zoological Park, Route 4, Box 83, Asheboro, North Carolina 27203, USA.

HEMIDACTYLIUM SCUTATUM (Four-toed Salamander). USA: NORTH CAROLINA: Richmond Co: 12.7 km WNW Ellerbe. 21 November 1992. J. C. Beane and S. L. Alford. Verified by A. L. Braswell. North Carolina State Museum of Natural Sciences (NCSM 32001). Adult taken AOR; new county record (NCSM files).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611, USA, and **STANLEY L. ALFORD**, North Carolina Zoological Park, Route 4, Box 83 Asheboro, North Carolina 27203, USA.

PLETHODON GLUTINOSUS (Northern Slimy Salamander). USA: ILLINOIS: Fayette Co: NW 1/4 Sec. 7, T8N, R1W, Ramsey Lake State Park. 19 April 1992. M. Bavetz. Verified by Ronald A. Brandon. Southern Illinois University Department of Zoology Collection (SIUC H–4116). County record (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298).

Submitted by **MARK J. BAVETZ**, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA.

PLETHODON YONAHLOSSEE (Yonahlossee Salamander). USA: NORTH CAROLINA: Surry Co: 3.2 km SW Low Gap. 13 September 1992. J. C. Beane, A. B. Somers et al. Verified by W. M. Palmer. North Carolina State Museum of Natural Sciences (NCSM 31861). One of four adults observed at same locality. New county record; extends range ca. 12.6 km E of nearest records in Alleghany County (NCSM files). Funding for field work resulting in this discovery was provided by the Surry County Natural Areas Inventory; we thank Porter Lowe and William Hoge for private land access.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611, USA, and **ANN BERRY SOMERS**, Department of Biology, University of North Carolina at Greensboro, Greensboro, North Carolina 27412–5001, USA.

ANURA

ASCAPHUS TRUEI (Tailed Frog). USA: WASHINGTON: Pacific Co: tributary of Willapa River, 2.5 km S Rt. 6 (SW 1/4 Sec. 2, T12N, R8W). 15 August 1992. M. J. Adams. Verified by R. B. Bury. U.S. Biological Survey Collection, Fort Collins, Colorado (VS/FC 7054). First record for county and for the Willapa Hills. Fills ca. 140 km gap in coastal distribution (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press, Moscow, 332 pp.). The Willapa Hills have been heavily logged. However, on the tributary where the frog was collected there is a stream buffer-zone (ca. 100 m each side) and much of the timber surrounding its headwaters is uncut. These factors may have helped preserve this population (Corn and Bury 1989, Forest Ecol. Management 29:39–57.).

Submitted by **MICHAEL J. ADAMS**, U.S. Fish and Wildlife Service, National Ecology Research Center, 4512 McMurry Avenue, Fort Collins, Colorado 80525–3400, USA, and **ALBERT G. WILSON, JR.**, Department of Zoology, Washington State University, Pullman, Washington 99164–4236, USA.

BUFO TERRESTRIS (Southern Toad). USA: LOUISIANA: Sabine Co: 10 km N Lake Hornbeck. 6 July 1929. AMNH 32662–63; Calcoasieu Co: 10 km N Lake Charles. 5 July 1929. AMNH 32648. All specimens collected by C. E. and M. D. Burt. All verified by L. Lee Grismer. New county records and first records from W Louisiana. Extends the range westward ca. 160 km (Blem 1979, *Bufo terrestris*, Cat. Amer. Amphib. Rept. 223.1–223.4; Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.). In addition, on the night of 31 May 1992, two DOR Louisiana *Bufo terrestris* were found but not collected; one near Peason, Sabine County, and the second near Reeves, Allen County.

Submitted by **ERIK W. A. GERGUS**, Department of Biology, College of Sciences, San Diego State University, San Diego, California 92182–0057, USA.

HYLA AVIVOCA (Bird-voiced Treefrog). USA: LOUISIANA: Tensas Parish: Big Lake State Wildlife Refuge (NW 1/4 of NW 1/4 of Section 6, T13N, R9E). 7 June 1990. Lance Gorham and Ed Trahan. Verified by Douglas A. Rossman. Northeast Louisiana University Museum of Herpetology (NLU 70369). New parish record; significant range extension into NE Louisiana along the Tensas River drainage. (Dundee and Rossman 1989, The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge, Louisiana, 300 pp.).

Submitted by **LANCE E. GORHAM** and **STEVE JENSEN**, Department of Biology, Northeast Louisiana University, Monroe, Louisiana 70201, USA.

HYLA CINEREA (Green Treefrog). USA: KENTUCKY: Trigg Co: Land Between The Lakes, E side of Kentucky Lake at river mile 49.0, S side of Jones Creek just E of where it enters Jones Creek Bay (36°40'46"N, 88°02'59"W). 10 June 1992. John Koons and Floyd Scott. Verified by David H. Snyder. Austin Peay State University Museum of Zoology (APSU 4597). Adult male among emergent vegetation at side of stream, many more calling around head of bay. New county record and first record from Kentucky portion of Tennessee River drainage basin (Kentucky State Nature Preserves Commission, Natural Heritage Program, Element Occurrence Records).

Submitted by **A. FLOYD SCOTT**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA, and **JOHN KOONS**, Department of Natural and Physical Sciences, Jackson State Community College, Jackson, Tennessee 38301, USA.

HYLA CINEREA (Green Treefrog). USA: TENNESSEE: Stewart Co: Land Between The Lakes (LBL), Rushing Creek Campground, E shore of Kentucky Lake at river mile 50.0 on N side of small stream that enters Skunk Hollow Bay (36°40'11"N, 88°03'04"W), adult male in dead black willow tree (*Salix nigra*). 7 June 1992. John Koons. Austin Peay State University Museum of Zoology (APSU 4580); LBL, E side of Kentucky Lake at river mile 54.2 on S shore of Clay Bay (36°36'36"N, 88°01'48"W), adult male on ground just above waterline at base of wooded hillside (many more calling from emergent vegetation around head of bay). 11 June 1992. Floyd Scott. APSU 4581. Both specimens verified by David H. Snyder. First records for LBL and Stewart County, and first records E of Tennessee River in Tennessee (Snyder 1972, Amphibians and Reptiles of Land Between The Lakes, Tennessee Valley Authority, Golden Pond, Kentucky, 90 pp.; Redmond 1985, A Biogeographic Study of Amphibians in Tennessee, Doctoral Thesis, Univ. Tennessee, Knoxville, 290 pp.).

Submitted by **A. FLOYD SCOTT**, Department of Biology and Center for Field Biology, Austin Peay State University, Clarksville, Tennessee 37044, USA, and **JOHN KOONS**, Department of Natural and Physical Sciences, Jackson State Community College, Jackson, Tennessee 38301, USA.

HYLA CINEREA (Green Treefrog). USA: TEXAS: Kaufman Co: East bank Cedar Creek, 0.8 km N US Rt. 175, 3.5 km SE US Rt. 175–FM 1391 jct. in Kemp. 13 September 1992. John S. McCord, Jr. Verified by William J. Voss. Fort Worth Museum of Science and History (FWM 10987). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press. College Station, Texas. 434 pp.); completes distribution records for counties immediately SE of Dallas County (Cobb and Cobb 1991, Herpetol. Rev. 22(1):27–28 and Roberts and Shilling 1991, Herpetol. Rev. 22(3):102.).

Submitted by **JOHN S. McCORD, JR.**, 1624 Martha Drive, Bedford, Texas 76022, USA.

HYLA SQUIRELLA (Squirrel Treefrog). USA: TEXAS: Nueces Co: Mustang Island: Port Aransas, grounds of University of Texas Marine Science Institute. 19 September 1992. John S. McCord, Jr., Eric N. Smith, Karin S. Castañeda. University of Texas at Arlington collection of Vertebrates (UTA A–38890–93). Verified by Jonathan A. Campbell; and Fort Worth Museum of Science and History (FWM 10990–94). Verified by William J. Voss. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press, College Station, Texas. 434 pp.); fills gap between Kleberg and San Patricio counties at the southern portion of this frog's range in Texas. UTA specimens were one adult female (with eggs) and an adult male found in leaf axils of garden palms near faucet (2030 h), and two juveniles active on low vegetation over a small puddle in second growth and grass (2130 h). The FWM specimens (two adult males, one gravid female, and three juveniles) were active at night on walls and windows between 0.1 and 2 m above ground.

Submitted by **JOHN S. McCORD, JR.**, 1624 Martha Drive, Bedford, Texas 76022, **KARIN S. CASTAÑEDA** and **ERIC N. SMITH**, Department of Biology, The University of Texas at Arlington, Arlington, Texas 76019, USA.

PSEUDACRIS CLARKII (Spotted Chorus Frog). USA: TEXAS: Mills Co: West side of Texas Rt. 16, 1.4 km S Texas Rt. 16–FM 218 jct. in Priddy. 30 May 1992. John S. McCord, Jr. Verified by Wesley A.

M. Hathaway. Fort Worth Museum of Science and History (FWM 10916–18). All specimens were males collected from a small chorus that was first heard about 1915 h on a cloudy day before sunset. New county record; partly fills a distributional gap in a three county area of central Texas (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press, College Station, Texas. 434 pp.).

Submitted by **JOHN S. McCORD, JR.**, 1624 Martha Drive, Bedford, Texas 76022, USA.

RANA CLAMITANS MELANOTA (Green Frog). USA: MISSOURI: Pike Co: under rocks at edge of slow stream that forms the northern boundary of Traynor and Traynor Farms, ca. 5.5 km NW Curryville, N 1/2, NE 1/4, NW 1/4 Sec. 18, T53N, R4W. 23 August 1992. Brian S. Edmond. University of Missouri, Columbia (UMC 1322A & 1323A). Verified by D. E. Metter. New county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

SYRRHOPHUS CYSTIGNATHOIDES CAMPI (Rio Grande Chirping Frog). USA: TEXAS: Nueces Co: Mustang Island, Port Aransas, grounds of the University of Texas Marine Science Institute, at loading dock beside Security Office. 17 September 1992. Fort Worth Museum of Science and History (FWM 10988); Mustang Island, Port Aransas, grounds of the University of Texas Marine Science Institute, beneath Dormitory A. 18 September 1992. (FWM 109089). Both collected by John S. McCord, Jr. Both verified by William J. Voss. Many of these frogs were heard calling, both on the Institute grounds, as well as in Port Aransas proper. That choruses heard were this species' was confirmed when FWM 10989 began calling in a markedly similar fashion from its bag after being collected. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press. College Station, Texas, 434 pp.); adds authenticity to an additional introduced population (*sensu* Dundee 1991. Herpetol. Rev. 22(4):122) roughly intermediate between the lower Rio Grande and one in Houston and San Antonio (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.).

Submitted by **JOHN S. McCORD, JR.**, 1624 Martha Drive, Bedford, Texas 76022, USA.

XENOPUS LAEVIS (African Clawed Frog). USA: COLORADO: Summit Co: SE side of US Rt. 6, 14.5 km NE Keystone, 3150 m elev. (39°53'33"N, 105°56'58"W). 5 June 1990. S. T. Bacchus (UF Photograph 86757 by K. Richter). Verified by Hobart M. Smith. State record; released, possibly recently. The colonized range of this introduced species in the United States has been reported for California and Arizona (Stebbins 1985, A Field Guide to Western Reptiles and Amphibians. 2nd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.; Mooney et al. 1986, pp. 250–272. *In* H. A. Mooney and J. A. Drake (eds.), The Ecology of Biological Invasions of North America and Hawaii. Springer-Verlag, New York). Found partially hidden under a submerged log in a tiered series of relic beaver ponds along the North Fork of the Snake River in the Arapaho Basin. The specimen did not have conspicuous claws. The water in the upper levels of the beaver pond complex remained partially frozen on this date, with a consistency of slush; however, during the extended photo session the frog swam freely in the frigid water, periodically burrowing headfirst into mats of aquatic vegetation. During 1–2 June 1991 the site was revisited by Bacchus and Moler, but no frogs were found.

Submitted by **SYDNEY T. BACCHUS**, Institute of Ecology, University of Georgia, Athens, Georgia 32602–2202, USA; **KLAUS RICHTER**, Parks, Planning and Resources Department, 3600–136th Place SE, Bellevue, Washington 98006–1400, USA; and **PAUL MOLER**, Wildlife Research Lab, Florida Game and Fresh Water Commission, 4005 South Main Street, Gainesville, Florida 32601, USA.

TESTUDINES

CLEMMYS INSCULPTA (Wood Turtle). CANADA: ONTARIO: Simcoe Co: Nottawasaga River, Minesing Swamp, 9 km N Angus (44°24'04"N, 79°53'19"W). 12 July 1992. Robert L. Bowles, Carolyn King, Harry Hall, et al. Royal Ontario Museum, Toronto (ROM 22638-39; photographs; protected species under Ontario Game and Fish Act). Verified from photos by W. F. Weller and R. D. MacCulloch. First verified record for county; observed previously in Minesing Swamp by R. H. Curry in June 1988, ca. 3 km to SSW. Fills significant gap in known distribution in southern Ontario (Logier and Toner 1961, Check List of the Amphibians and Reptiles of Canada and Alaska. Life Sciences Division, Contr. 53, Royal Ontario Mus., 92 pp.; Oldham and Weller, unpubl. computer database of Ontario specimen and observation records). In conjunction with localities near Lake Huron (ca. 115 km to W), near E shore of Lake Simcoe (ca. 70 km to NE; ROM 22640), and E of Algonquin Provincial Park (ca. 265 km to NE), represents a northern limit record at this longitude in southern Ontario.

Submitted by **ROBERT L. BOWLES**, 374 Grenville Avenue, Orillia, Ontario L3V 7P7, Canada.

PELODISCUS SINENSIS (Chinese Softshell). USA: GUAM: Mariana Islands, Umatac Municipality, between Umatac Bay and confluence of Madog and Laelae rivers. January 1992. Anonymous donation to Steve Nussbaum. Verified by Thomas H. Fritts. Michael J. McCoid Collection (MJM 3096; deposited at USNM). While there have been a number of sightings of this species in eastern and southeastern Guam (McCoid, Herpetol. Rev., *in press*), this specimen represents the first verified record for the island and indicates that the species may be fairly widespread in central and southern Guam.

Submitted by **EARL W. CAMPBELL III**, Ohio Cooperative Fish and Wildlife Research Unit, 1735 Neil Avenue, Columbus, Ohio 43210, USA, and **MICHAEL J. McCOID**, Route 1, Box 143, Edinburg, Texas 78439, USA.

PHRYNOPS WILLIAMSI (Williams' South American Sideneck Turtle). ARGENTINA: CORRIENTES: Departamento Ituzaingó, Puerto Valle (27°36'S, 56°26'W) on the Paraná River bank. 19 January 1990. A. Giraudo. Verified by M. S. De La Fuente. Herpetological Collection of Dept. Biodiversidad y Ecología, Universidad Nacional de Córdoba, Argentina (C–288). A hatchling, taken as an egg in a group of five when its nest was predated by a bird (Aramidae); when handled, four of them immediately hatched. First record for the Provincia de Corrientes; confirms presence in the province as suggested by Rhodin and Mittermeier (1983, pp. 58–73 *In* Rhodin and Miyata, eds., Advances in Herpetology and Evolutionary Biology, Publ. Mus. Comp. Zool., Harvard), but within the Paraná River basin. Second Argentine province, species previously recorded for Misiones (Richard and De La Fuente 1987, published 1992, Acta Zool. Lilloana, 41:357–364). Extends range ca. 260 km air line from the nearest verified population at Misiones, Arroyo Urugua-i (MACN–12589/12595). Thanks to the Secretaría de Ciencia y Tecnologia Provincia de Córdoba for financial support.

Submitted by **MARIO R. CABRERA**, Departamento Biodiver-

sidad y Ecología, Universidad Nacional de Córdoba, Vélez Sarsfield 299, 5000 Córdoba, Argentina.

LACERTILIA

ANELYTROPSIS PAPILLOSUS (Mexican Blind Lizard). MÉXICO: HIDALGO: Municipality of Chapulhuacan, Cerro de la Joya, 4 km SSW Arroyo Blanco (21°07'N, 98°54'W) 400 m elev. 29 May 1992. Efraín Hernández and Fernando Mendoza. Museo de Zoología, Facultad de Ciencias, UNAM, MZFC 05388, (155 mm SVL, 180 mm TL) and MZFC 05389 (150 mm SVL, 205 mm TL). Verified by O. Flores-Villela. Found under large sedimentary boulders in tropical deciduous forest although the microhabitat was sheltered and moist. *Leptotyphlops dulcis myopicus* was collected in similar nearby habitat which suggests syntopy. First record for the state of Hidalgo and a southern range extension of 18 km SE and 30 km SW from records in nearby extreme eastern Querétaro and San Luis Potosí, respectively; confirms prediction of Campbell (1974, Cat. Amer. Amph. Rept. 156:1-2) that this species would be found in adjacent northern Hidalgo.

Submitted by **FERNANDO MENDOZA QUIJANO**, Museo de Zoología, Facultad de Ciencias, UNAM Apdo. Post. 70-399, México, Distrito Federal 04510, México, **EFRAÍN HERNÁNDEZ GARCIA**, Calandria No. 23-1, Unidad Independencia, Contreras, México, Distrito Federal 10100, México, and **WALTER SCHMIDT BALLARDO**, Adolfo Prieto No. 819, Col. del Valle, México, Distrito Federal 03100, México.

CNEMIDOPHORUS EXSANGUIS (Chihuahuan Spotted Whiptail). USA: NEW MEXICO: Rio Arriba-Taos county line: Carson National Forest, 3.2 km above (presumably W of) Servilleta. 14 May 1937. Collector unknown. Verified by W. G. Degenhardt. UMMZ 84290 (3 specimens). County is indeterminate, however, this locality is the northernmost for the species and extends range ca. 50 km N from SE Rio Arriba County (Stuart 1991, Cat. Amer. Amphib. Rept.: 516.1–516.4).

Submitted by **JAMES N. STUART**, Museum of Southwestern Biology, University of New Mexico, Albuquerque, New Mexico 87131, USA.

CNEMIDOPHORUS SEXLINEATUS VIRIDIS (Prairie Racerunner). USA: TEXAS: Hall Co: old railroad bed 0.4 km W US Rt. 287, 1.6 km S middle of Red River bridge. 29 September 1992. H. M. Smith. Verified by Richard L. Holland. UCM 56620. First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M Press, College Station, Texas, 434 pp.); partially fills hiatus between panhandle and other records.

Submitted by **HOBART M. SMITH**, Department of EPO Biology and Museum, University of Colorado, Boulder, Colorado 80309–0334, USA.

EUMECES FASCIATUS (Five-lined Skink). USA: MISSOURI: Pike Co: in forest on southern half of Traynor and Traynor Farms, ca. 5.5 km NW Curryville, NE 1/4 NW 1/4 NW 1/4 Sec. 18, T53N, R4W. 21 August 1992. Brian S. Edmond. University of Missouri, Columbia (UMC 633L). Verified by D. E. Metter. New county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

EUMECES MULTIVIRGATUS MULTIVIRGATUS (Northern Many-lined Skink). USA: COLORADO: Kiowa Co: 1.6 km S Cheyenne County line along US Rt. 287. 22 July 1992. Richard L Holland & Hobart M. Smith. Verified by David Chiszar. UCM 56614. First county record (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, 120 pp.); extends known range of species eastward ca. 95 km into the southeastern corner of the state.

Submitted by **HOBART M. SMITH**, Department of EPO Biology and Museum, University of Colorado, Boulder, Colorado 80309–0334, USA, and **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA.

EUMECES OBSOLETUS (Great Plains Skink). USA: COLORADO: Cheyenne Co: 15.2 m N County Rd A, 1.6 km E US Rt. 287. 22 July 1992. Richard L. Holland & Hobart M. Smith. Verified by David Chiszar. UCM 56615. First county record (Hammerson 1982, Amphibians and Reptiles in Colorado. Colorado Division of Wildlife, 129 pp.); partially fills hiatus between NE and SE records in Colorado (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.).

Submitted by **RICHARD L. HOLLAND**, Science Department, Boulder High School, 1604 Arapahoe Avenue, Boulder, Colorado 80302, USA, and **HOBART M. SMITH**, Department of EPO Biology and Museum, University of Colorado, Boulder, Colorado 80309–0334, USA.

HEMIDACTYLUS MABOUIA (Tropical House Gecko). USA: FLORIDA: Monroe Co: Bahia Honda Key, Bahia Honda State Recreation Area. 26–27 June 1991. A. Bauer, R. Günther & D. King. Verified by K. de Queiroz. Zoologisches Museum, Berlin (ZMB 48893, 48920, 49204–5, 50805). Adults and juveniles collected on walls of buildings and on path near eastern end of key. Extends known range in the Florida Keys 25 km southwest from only other U.S. record on Crawl Key (Lawson et al. 1991, Herpetol. Rev. 22:11–12). Increases to nine the number of lizard species recorded from Bahia Honda (Anonymous, no date, Vertebrates Identified in Bahia Honda State Recreation Area, Publ. Florida Dept. of Natural Resources, Tallahassee).

Submitted by **RAINER GÜNTHER**, Zoologisches Museum, Museum für Naturkunde der Humboldt-Universität zu Berlin, Invalidenstraße 43, D(O) 1040 Berlin, Germany, **AARON M. BAUER** and **DAVID KING**, Biology Department, Villanova University, Villanova, Pennsylvania 19085, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Pecos Co: KOA Campground, N of Interstate 10–US 385/US 290 (Dickinson Street) jct. in Fort Stockton. 1 August 1992. Kevin W. C. Pajak and John S. McCord, Jr. Verified by William J. Voss. Fort Worth Museum of Science and History (FWM 10928). New county record; extends range 53.8 km NE Brewster County (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press. College Station, Texas, 434 pp.).

Submitted by **KEVIN W. C. PAJAK**, 8991 Meadowbrook Way, Buena Park, California 90621, USA, and **JOHN S. McCORD, JR.**, 1642 Martha Drive, Bedford, Texas 76022, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: De Witt Co: Yorktown, inside former Yorktown Theatre Building, jct. Texas Rts. 72 and 119. 28 August 1992. James D. Ponder. Verified by James R. Dixon. Texas Cooperative Wildlife Collection (TCWC 70017). New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press, College Station, Texas, 434 pp.).

Submitted by **R. KATHRYN VAUGHAN**, Department of Wildlife and Fisheries Sciences, Texas A & M University, College Station, Texas 77843, USA.

HEMITHECONYX CAUDICINCTUS (African Gecko) CAMEROON: GAROUA: North Cameroon. Collected by Mouchet. No date. Muséum National d'Histoire Naturelle, Paris 8749; Cameroon. No collector and no date. MNHN 8687; Cameroon. Collected by Stauch. No date. MNHN 1967–249 and 250; North Cameroon, Garoua, "Ecole de Faune." Collected by Hubert Planton. 15 March 1992. MNHN 1992–5245. All verified by Georges Pasteur. New country record (Loveridge 1947, Bull. Mus. Comp. Zool. Harvard 98:1–469; Perret 1963, Rev. suisse Zool. 70(3):47–60). Previously known from "Nigeria west to Senegal."

Submitted by **IVAN INEICH**, Muséum National d'Histoire Naturelle, Laboratoire de Zoologie (Reptiles et Amphibiens), 25 Rue Cuvier, F–75005 Paris, France.

SCELOPORUS UNDULATUS CONSOBRINUS (Southern Prairie Lizard). USA: TEXAS: Knox Co: 1.6 km W Munday, Road 222. 2 October 1983. G. Wallins. West Texas State University (WTSU 9527); Moore Co: Blue West Recreation Area, Lake Meredith. 21 May 1983. J. Vines. WTSU 9557; Potter Co: Amarillo area. WTSU 10802, Rivera Park, 16 km N Amarillo. 17 & 28 April 1987. B. Loving. WTSU 8312. 4.8 km N Bushland, Road 2381. 16 March & 5 April 1981. R. Walsh, B. Hayes, & T. James. WTSU 6687–9. Road 1061, 9 km W Road 2381. 16 November 1969. T. Rush. WTSU 263–264, Plum Creek Recreation Area, Lake Meredith. 20–22 September 1979, 21 May 1983, 25 April 1987. K. Brewer, B. May, T. Payne, M. L. Simmons, J. and J. Vines and W. Willis. WTSU 5944, 6003, 6092–4, 6127–31, 10608, 14289. All verified by Edwin L. Bell. First county records (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press, College Station, 434 pp.).

Submitted by **KATHLEEN BLAIR**, Department of Biology and Geosciences, West Texas State University, Canyon, Texas 79015–0808, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309–0334, USA.

SCELOPORUS UNDULATUS GARMANI (Northern Prairie Lizard). USA: TEXAS: Hansford Co: Rue and Rex Sanders Ranch, Road 2387, 7.8 km N jct. with Road 15. 22 August 1978. Flavius C. Killebrew. Verified by Edwin L. Bell. West Texas State University (WTSU 5863). First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press, College Station, 434 pp.).

Submitted by **KATHLEEN BLAIR**, Department of Biology and Geosciences, West Texas State University, Canyon, Texas 79015–0808, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309–0334, USA.

SCELOPORUS UNDULATUS HYACINTHINUS (Northern Fence Lizard). USA: PENNSYLVANIA: Schuylkill Co: Middle Creek, 3.2 km N Tremont, Frailey Twp. 2 August 1992. Craig A. Heinsohn. CM 125799. Verified by C. J. McCoy. Female, 73 mm SVL, 90 mm tail length. New county record (McCoy 1982, Amphibians and Reptiles in Pennsylvania. Carnegie Mus. Spec. Publ. 6). Extends range ca. 32 km NE from nearest locality in Lebanon County. Two other females were found by Heinsohn in the same county, one near Lincoln, Tremont Township, 5 September 1991, and one near Middle Creek, Frailey Township, in June 1992; both were released.

Submitted by **EDWIN L. BELL**, P. O. Box 15234, Albright College, Reading, Pennsylvania 19612–5234, USA.

SCINCELLA LATERALIS (Ground Skink). USA: MISSOURI: Pike Co: in forest on western boundary line of Ranacker Wildlife Area, ca. 4 km S Frankford. NW 1/4, NW 1/4, SW 1/4 Sec. 13, T54N, R4W. 22 August 1992. Brian S. Edmond. University of Missouri, Columbia (UMC 634L); in pasture (on edge of woods) of NE portion of Traynor and Traynor Farms, ca. 5 km NW Curryville. NE 1/4, SW 1/4, NW 1/4 Sec. 18, T53N, R4W. 22 August 1992. Brian S. and Kellie Jayne Edmond. UMC 635L. Both verified by D. E. Metter. New county records (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

SERPENTES

ELAPHE EMORYI (Great Plains Rat Snake). USA: KANSAS: Sheridan Co: Ks. Rt. 23 at State Wildlife Area. 7 June 1992. Travis W. Taggart. Verified by Joseph T. Collins. KU 220601. New county record (Collins 1982, Amphibians and Reptiles in Kansas. Second ed. Univ. Kansas Mus. Nat. Hist. Pub. Ed. Ser. 8:1–356).

Submitted by **TRAVIS W. TAGGART**, 2302 Donald Drive, Hays, Kansas 67601, USA.

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). USA: TEXAS: Hansford Co: Gibbner Ranch, 16.2 km N Spearman, Road 760. 12 August 1978. F. C. Killebrew. Verified by Richard L. Holland. West Texas State University (WTSU 5004). First county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A & M University Press, College Station, 434 pp.).

Submitted by **KATHLEEN BLAIR**, Department of Biology and Geosciences, West Texas State University, Canyon, Texas 79015–0808, USA, **JAMES R. STALEY II**, Colorado Division of Wildlife, Central Region, 6060 Broadway, Denver, Colorado 80216, USA, and **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309–0334, USA.

HETERODON PLATIRHINOS (Eastern Hognose Snake). USA: PENNSYLVANIA: Schuylkill Co: 1.6 km W Port Clinton on the old Schuylkill Canal towpath. 17 May 1992. Edwin L. Bell. Verified by C. J. McCoy. CM 125767. Melanistic female with orange crossbars; 778 mm SVL, 103 mm tail length. Previously reported from surrounding counties: Berks, Northumberland, and Carbon (McCoy 1982, Amphibians and Reptiles of Pennsylvania, Carnegie Mus. Spec. Publ. No. 6).

Submitted by **EDWIN L. BELL**, P.O. Box 15234, Albright College, Reading, Pennsylvania 19612–5234, USA.

LAMPROPELTIS GETULA CALIFORNIAE (California Kingsnake). MÉXICO: SONORA: Isla San Esteban, Gulf of California. 13 September 1990. Kent R. Beaman and L. Lee Grismer. Verified by Tom Van Devender. Arizona-Sonora Desert Museum, Tucson, Arizona. LACM voucher photographs 140090, 140091. First known live records of this species from Isla San Esteban; adult male and female from Arroyo Limantur on E side of island on eve of a storm; currently alive in the Centro Ecologico de Sonora, Hermosillo, Sonora, México (Murphy and Ottley 1984, Distribution of Amphibians and Reptiles on Islands in the Gulf of California. Ann. Carnegie Mus. 53:207–230.). Previously only known on island from a shed skin found 21 October 1986 by Rogelio Molina-Freaner (presented in paper by Lara and Lawler at 1987 SSAR/HL meeting).

Submitted by **GUILLERMO LARA-GONGORA**, Apartado Postal 57–305, México, Distrito Federal cp 06501, México, **KENT R. BEAMAN**, Section of Herpetology, Los Angeles County Natural

History Museum, 900 Exposition Boulevard, Los Angeles, California 90007, USA, **L. LEE GRISMER**, Department of Biology, San Diego State University, San Diego, California 92182, USA, and **HOWARD E. LAWLER**, Arizona-Sonora Desert Museum, 2021 North Kinney Road, Tucson, Arizona 85743, USA.

NERODIA RHOMBIFER (Diamondback Water Snake). USA: MISSOURI: Pike Co: crossing road in bottoms, just S Ted Shanks Wildlife Area Visitor Center, ca. 1 km SE Ashburn. SW 1/4, NE 1/4 Sec. 18, T55N, R2W. 4 October 1992. Brian S. Edmond. University of Missouri, Columbia (UMC 774S). Verified by D. E. Metter. New county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

NERODIA SIPEDON SIPEDON (Northern Water Snake). USA: MISSOURI: Pike Co: on banks of creek that forms the NW boundary of Traynor and Traynor Farms, ca. 5.5 km NW Curryville. NE 1/4, SE 1/4, SE 1/4 Sec. 12 , T53N, R5W. 21 August 1992. Brian S. Edmond. University of Missouri, Columbia (UMC 771S); crossing road in bottoms, just S Ted Shanks Wildlife Area Visitor Center, approximately 1 km SE Ashburn. SW 1/4, NE 1/4 Sec. 18, T55N, R2W. 4 October 1992. Brian S. Edmond. UMC 775S. Both verified by D. E. Metter. New county records (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). USA: FLORIDA: Pinellas Co: St. Petersburg, between 22 Avenue N & 28 Avenue N, 0.31 air km W Interstate Rt. 275 & ca. 0.10 air km E of Seaboard Coast Line Railroad, NE corner Sec. 11, T31S, R16E. 6 November 1992, 11 November 1992. D. M. Crawford. Verified by David L. Auth. Florida Museum of Natural History (UF 86601, 86602, 86603, 86604 & 86605). Five subadults beneath bricks, discarded rug and trash can lid in isolated hardwood hammock surrounded by urban and suburban development. Six additional subadults are being kept alive in the personal collection of D. M. Crawford. Eleven individuals sighted but evaded capture. All found among ant colonies (probably *Monomorium* sp.) beneath anthropogenic debris. First county record; extends range ca. 177 air km N of record in Ft. Myers, Lee County, along the west coast of Florida (Conant and Collins 1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed., Houghton Mifflin Co., Boston, Massachusetts, 450 pp.), and ca. 111 air km ENE of nearest record in Avon Park, Highlands County, southcentral Florida (UF 81952–3), thus making this the northernmost record in Florida. Other U.S. records of this secretive, parthenogenic exotic include Coral Gables, Hialeah, Homestead, Miami (Dade County), Lake Okeechobee (Palm Beach County), and Key West (Old Town) and Big Pine Key (Monroe County), Florida (Delorey and Mushinsky 1987, Herpetol. Rev. 18:56; Ehrig 1990, Herpetol. Rev. 21:41; Wilson and Porras 1983, Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9:1–89; Wynn et al. 1987, Amer. Mus. Novit. 2868:1–7), and Boston, Massachusetts (Wallach et al. 1991, Herpetol. Rev. 22: 68).

Submitted by **DANIEL M. CRAWFORD**, 13521-120th Lane North, Largo, Florida 34648, USA, and **LOUIS A. SOMMA**, Department of Zoology, University of Florida, Gainesville, Florida 32611, USA.

REGINA GRAHAMII (Graham's Crayfish Snake). USA: MISSOURI: Pike Co: crossing road in bottoms, just S Ted Shanks Wildlife Area Visitor Center, ca. 1 km SE Ashburn. SW 1/4, NE 1/4 Sec. 18, T55N, R2W. 10 August 1992. Brian S. Edmond. University of Missouri, Columbia (UMC 769S). Verified by D. E. Metter. New county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

RHADINAEA MONTECRISTI (NCN). HONDURAS: COMAYAGUA: Cordillera de Montecillos, 1.7 km N and 0.1 km W Cerro San Juanillo, elev. 1960 m. 18 June 1991. P. Holm. Verified by Gustavo A. Cruz. Universidad Nacional Autonoma de Honduras (UNAH 2742). Extends known range of species E by ca. 100 km; previously known only from extreme NW El Salvador and SW Honduras (McCranie and Wilson 1991, Cat. Amer. Amphib. Rept. 524:1–2). Specimen (adult female, live mass 11.7 g, SVL 309 mm, tail 123 mm; ventrals 173, subcaudals 78) was active on leaf litter in mature cloud forest. It is syntopic with *R. godmani* (UNAH 2717) at this locality.

Submitted by **PETER HOLM**, Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, Arizona 85721, USA.

STORERIA OCCIPITOMACULATA OCCIPITOMACULATA (Northern Redbelly Snake). USA: MISSOURI: Pike Co: under flat rock at JC & SM Edmond home, ca. 7 km NNW Curryville. NE 1/4, NW 1/4, NE 1/4 Sec. 5, T53N, R4W. 23 August 1992. Brian S. Edmond. University of Missouri, Columbia (UMC 772S). Verified by D. E. Metter. New county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

STORERIA OCCIPITOMACULATA (Redbelly Snake). USA: OKLAHOMA: Cherokee Co: near Scraper. 14 April 1962. W. A. Carter. East Central Univ. Biol. Coll. (ECU 1986); 17.7 km E Tahlequah. 1 May 1970. W. A. McCracken. ECU 1990. Verified by W. A. Carter and J. H. Black. These vouchers verify previous reports in Cherokee County (Secor and Carpenter 1985, Distribution Maps of Oklahoma Reptiles. Okla. Herp. Soc. Spec. Publ. 3:1–57); Atoka Co: 29 km NE Atoka. 2 October 1989. B. Pitman. ECU 2346; Pittsburg Co: Collins Wildlife Refuge. 11 November 1989. A. Black. ECU 2347. Verified by W. A. Carter and J. H. Black. New county records; extend known distribution W in Oklahoma (Secor and Carpenter, op. cit.). Rossman and Erwin (1980, Brimleyana 4:95–102) and Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.) indicate two subspecies occur in Oklahoma—*S. o. occipitomaculata* in NE Oklahoma and *S. o. obscura* in SE Oklahoma, where it integrades with *S. o. occipitomaculata*. Subspecific status of these specimens was not determined.

Submitted by **CHARLES B. SHANS**, Department of Biology, East Central University, Ada, Oklahoma 74820, USA.

TANTILLA GRACILIS (Flathead Snake). USA: MISSOURI: Montgomery Co: on small glade near road, 0.5 km SE campground, Danville Wildlife Area, ca. 3 km SSE Danville. SW 1/4 NW 1/4 SW 1/4 Sec. 5, T47N, R5W. 30 September 1992. Brian S. and Kellie Jayne Edmond. University of Missouri, Columbia (UMC 773S). Verified by D. E. Metter. New county record and first Missouri specimen collected N of Missouri River (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

THAMNOPHIS RADIX RADIX (Eastern Plains Garter Snake) USA: Montgomery Co: NW 1/4 Sec. 3, T10S, R5W, at rest stop on I–55. 11 April 1992 M. Bavetz. Verified by Ronald A. Brandon. Southern Illinois University Department of Zoology Collection (SIUC R–2359) County record; fills gap in SW Illinois between Madison and St. Clair counties (McNaughton 1976, Herpetol. Rev. 7(3):124) and SW edge of the range in Illinois as shown in Smith (1961, The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1–298), and Conant and Collins (1991, A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.).

Submitted by **MARK J. BAVETZ**, Department of Zoology, Southern Illinois University, Carbondale, Illinois 62901, USA.

VIRGINIA VALERIAE (Smooth Earth Snake). USA: MISSOURI: Pike Co: in forest of NE portion of Traynor and Traynor Farms, ca. 5 km NW Curryville, SE 1/4, NW 1/4, NW 1/4, Sec. 18, T53N, R4W. 22 August 1992. Brian S. and Kellie Jayne Edmond. University of Missouri, Columbia (UMC 770S). Verified by D. E. Metter. New county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Missouri Dept. Conserv., Jefferson City, 368 pp.).

Submitted by **BRIAN S. EDMOND**, 400 East Hinton Road, Apt. C, Columbia, Missouri 65201, USA.

BOOK REVIEWS

Second World Congress Of Herpetology Literature Review

With the Second World Congress of Herpetology in Adelaide, South Australia approaching it seems appropriate to provide *Herpetological Review* readers, and Congress-goers in particular, with a brief overview of recent books and booklets on the Australian herpetofauna. In the last decade Australia has probably produced more herpetological titles per capita than any other nation. Three of the most recent country-wide herpetofaunal guides by Hal Cogger, Harry Ehmann, and Mike Tyler are reviewed fully below. A number of other recent titles have been reviewed in *Herpetological Review* in the past. The following is an annotated list of some of the major (and not so major) Australian herpetological titles that have appeared since about 1980 (a few works from the late '70's are also included). Children's books and general works with only small sections on herpetology have been excluded and only the most recent editions of books are listed. Serendipitously, 64 titles are listed, one for each year since the publication of Edgar Waite's landmark *The Reptiles and Amphibians of South Australia*. The list provided is by no means complete, but it may serve at least as an introduction to the literature resources available to participants in the World Congress who want to maximize their appreciation of the unique Australian herpetofauna during their stay in Adelaide.

General Herpetologcal References (Amphibians and Reptiles)

COGGER, H. G. 1992. Reptiles and Amphibians of Australia, 5th edition. Ithaca: Cornell University Press. 775 pp. Hardcover. Species accounts for all Australian species, with color photos and shaded range maps. Introductory sections on general herpetological topics, extensive bibliography. Reviewed in this issue of HR.

COGGER, H. G., E. E. CAMERON, and H. M. COGGER. 1983. Zoological Catalogue of Australia, vol. 1, Amphibia and Reptilia. Canberra: Australian Government Publishing Service. 313 pp. Hardcover. Comprehensive technical guide with synonymies and literature guide for all Australian amphibians and reptiles.

GRIFFITHS, K. 1984. Reptiles and Frogs of Australia. Sydney: View Productions. 96 pp. Hardcover. Picture book.

HOSER, R. T. 1989. Australian Reptiles and Frogs. Sydney: Pierson and Co. 238 pp. Hardcover. Species accounts with color photos and shaded range maps for approximately 200 species. Includes sections on habitat types, photography, conservation, and captive care and husbandry. Reviewed by S. A. Minton, 1990, HR 21(4):97-98.

KENNEDY, M. (ed.). 1990. Australia's Endangered Species. Brookvale: Simon and Schuster Australia. 192 pp. Hardcover. Provides brief species accounts with shaded maps and some color photos for 39 endangered amphibian and reptile species. Complete listing of threatened and endangered species also given.

SCHMIDA, G. 1985. The Cold-Blooded Australians. Sydney: Doubleday Australia. 208 pp. Hardcover. Regional approach to representative fishes, amphibians, and reptiles. Reviewed by R. D. Bartlett, 1988, HR 19(4):88.

Frogs

TYLER, M. J. 1982. Frogs, 2nd edition. Sydney: Collins. 256 pp. Softcover. Biology of frogs with color photos and state checklists.

TYLER, M. J. (ed.) 1983. The Gastric Brooding Frog. London: Croom Helm. 163 pp. Hardcover. Collection of contributions on *Rheobatrachus silus*, with black and white photos and bibliography of the species.

TYLER, M. J. 1984. There's A Frog in My ~~Throat~~ Stomach. Collins: Sydney. 52 pp. Softcover. Non-technical book on *Rheobatrachus silus*, with color photos.

TYLER, M. J. 1989. Australian Frogs. Ringwood: Viking O'Neil. 220 pp. Hardcover. Biology of Australian frogs with emphasis on certain species. With black and white and color photos, extensive bibliography and many tables.

TYLER, M. J. 1992. Encyclopedia of Australian Animals: Frogs. Pymble: Angus and Robertson. 109 pp. Hardcover. Species accounts for all Australian frogs, with color photos and shaded range maps. Reviewed this issue of HR.

Reptiles (General)

BRADSHAW, S. D. 1986. Ecophysiology of Desert Reptiles. North Ryde: Academic Press Australia. 324 pp. Hardcover. Arid zone reptiles, with an emphasis on Australian lizards, especially agamids. Black and white photos and figures, extensive bibliography.

COGGER, H. G. 1989. Australian Reptiles in Colour, 2nd revised edition. Port Melbourne: Treasure Press. 112 pp. Hardcover. General overview of representative reptiles with color photos.

EHMANN, H. 1992. Encyclopedia of Australian Animals: Reptiles. Pymble: Angus and Robertson. 495 pp. Hardcover. Species accounts for all Australian reptiles, with color photos and shaded range maps. Reviewed this issue of HR.

HEATWOLE, H. F., and J. TAYLOR. 1987. Ecology of Reptiles. Chipping

Norton: Surrey Beatty and Sons. 325 pp. Hardcover. Detailed review of Australian reptile ecology, with extensive bibliography and some color plates.

WEIGEL, J. 1988. Care of Australian Reptiles in Captivity. Gosford: Reptile Keepers Association. 144 pp. Softcover. Guide to all aspects of captive care of commonly kept species, with black and white and color photos.

WILSON, S. K., and D. G. KNOWLES. 1988. Australia's Reptiles, A Photographic Reference to the Terrestrial Reptiles of Australia. Sydney: Collins. 447 pp. Hardcover. Species accounts, color photos, and shaded range maps for almost all reptile species.

Turtles

CANN, J. 1978. Tortoises of Australia. Sydney: Angus and Robertson. 79 pp. + 60 pp. pls. Softcover. Species accounts with many color photos and a section on captive care.

Crocodiles

HERMES, N. 1989. Crocodiles, Killers in the Wild. Frenchs Forest: Child and Associates. 64 pp. Hardcover. Chiefly (color) photography book.

WEBB, G., and C. MANOLIS. 1988. Australian Freshwater Crocodiles. Winnnellie: G. Webb Pty. Ltd. 32 pp. Softcover. Short overview of biology with color photos.

WEBB, G., and C. MANOLIS. 1988. Australian Saltwater Crocodiles. Winnnellie: G. Webb Pty. Ltd. 32 pp. Softcover. Short overview of biology with color photos.

WEBB, G., and C. MANOLIS. 1989. Crocodiles of Australia. Frenchs Forest: Reed Books. 160 pp. Hardcover. Covers biology, attack, human use, research, etc., with color photos.

Lizards

GREER, A. E. 1989. The Biology and Evolution of Australian Lizards. Chipping Norton: Surrey Beatty and Sons. 264 pp. Systematics, ecology, physiology, reproduction, etc. of Australian lizards. With line drawings, color photos, extensive bibliography and many tables.

SWANSON, S. 1987 [reprinted 1990]. Lizards of Australia, revised edition. North Ryde: Angus and Robertson. 160 pp. Softcover. Species accounts and color photos of selected species, with sections on captive care and photography.

Snakes (and Venoms)

CANN, J. 1986. Snakes Alive! Snake Experts and Antidote Sellers of Australia. Kenthurst: Kangaroo Press. 176 pp. Softcover. History of snake handlers in Australia, with many black and white photos.

COVACEVICH, J., P. DAVIE, and J. PEARN. (eds.). 1987. Toxic Plants and Animals, A Guide for Australia. South Brisbane: Queensland Museum. 504 pp. Softcover. Includes 12 papers on amphibians and reptiles, especially elapids, with emphasis on pharmacological and medical aspects of venoms and toxins. With many black and white photos and figures.

GARNET, J. R. 1981. Venomous Australian Animals Dangerous to Man. Parkville: Commonwealth Serum Laboratories. 88 pp. Species accounts with shaded maps and some black and white illustrations for some dangerously venomous species. Also includes venom and treatment information.

GOW, G. F. 1983 [reprinted 1991]. Snakes of Australia, revised edition. North Ryde: Angus and Robertson. 118 pp. + 48 pls. Softcover. Species accounts with color photos and a section on snake bite.

GOW, G. F. 1984. Australia's Dangerous Snakes. Sydney: Angus and Robertson. 80 pp. + 24 pp. pls. Softcover. Species accounts with color photos and shaded range maps and a section on snake bite.

GOW, G. F. 1989. Graeme Gow's Complete Guide to Australian Snakes. North Ryde: Angus and Robertson. 171 pp. Hardcover. Species accounts with keys, color photos and shaded range maps. Sections on snake bite and general biology of Australian snakes.

KREFFT, G. 1984 (reprint of 1869 edition). The Snakes of Australia. Brisbane: Lookout Publications. xxv + 100 pp. + 12 pls. Hardcover. Facsimile reprint with color plates. Reviewed by K. Adler, 1989, HR 20(1):21, 24.

LONGMORE, R. 1989. Snakes, Atlas of Elapid Snakes of Australia, revised edition. Australian Flora and Fauna Series No. 7. Canberra: Australian Government Publishing Service. 115 pp. Spiral bound. Biogeographic atlas of elapids with color photos and climatic parameters for all Australian species.

MIRTSCHIN, P., and R. DAVIS. 1983. Dangerous Snakes of Australia, revised edition. Adelaide: Rigby. 208 pp. Hardcover. Species accounts with venom information and color photos for dangerously venomous species. Extensive section on snake bite, venom, etc.

PEARN, J., and J. COVACEVICH. (eds). 1988. Venoms and Victims. South Brisbane: Queensland Museum Press. 136 pp. Softcover. Includes six papers on amphibians and reptiles, with an emphasis on venoms. Black and white and color photos, keys.

Reptiles and Amphibians of Australia, 5th ed., by Harold G. Cogger. 1992. Cornell University Press, Ithaca, New York. ISBN 0-8014-2739-8. 775 pp. $97.00 U.S. (Hardcover).

Seventeen years have elapsed since the publication of the first edition of Hal Cogger's classic work on the Australian herpetofauna. In the intervening period the number of described taxa in Australia has increased at an almost unbelievable rate. The first edition of the book (1975) treated 664 species, whereas the fourth (1986) included 865. The current version details over 950 amphibian and reptile taxa.

Each subsequent edition of Cogger's book has incorporated new taxa and reflected nomenclatural shifts occasioned by the ever more voluminous alpha systematic and phylogenetic work on the Australian herpetofauna. The fifth edition, however, is the first to deviate from its predecessors radically with respect to the layout style established in the original work. The effect is striking and, although there are some drawbacks, the net result is an improvement over older editions.

The main improvement in the new edition of the book is in the photography. The last edition of the book presented 224 color photos, arranged eight per plate. An additional 658 black and white photos, usually on neutral background were presented (three to eight per page) clustered at the back of the book. In the fifth edition each photograph appears within one or two pages of the text account of the same species. I counted 831 color photos and one black and white photo (*Varanus semiremex*) representing 738 species. The photographs, taken mostly by the author, range in quality from good to superb, with most hovering around "excellent." A few, such as that of *Eroticoscincus* (yes, that's its name) *graciloides*, are not particularly well cropped, and one photo of *Ramphotyphlops braminus* appears twice (pp. 590-591 and p. 732), apparently inadvertently. Most specimens illustrated, however, are presented attractively on naturalistic substrates and the photographs are well-centered and clearly show the diagnostic features of the animals. Unfortunately a reasonable number of photos spread onto two pages and are partially obscured by the binding. A few pages (e.g., pp. 324-325) feature photos that overlap one another. Although this style of presentation has become quite popular it does nothing to improve the transfer of information and detracts from the general layout quality.

The vast majority of all photographs are new to this edition. For example, of 98 color photographs of gekkonid lizards, only seven appeared in the fourth edition, and each of these has been improved as a result of larger, higher-resolution reproduction. In other parts of the book, however, photos are unnecessarily large and waste space. Keys have also been improved substantially by the addition of several hundred line drawings that illustrate many diagnostic features. Most of these are of high quality, but a few appear faded or are mislabeled and in at least five keys indicated figures are lacking or the existing figures are not correctly cited.

Little of the text has changed from the fourth edition. Introductory sections dealing with nomenclature, distribution, specimen identification, conservation, habitat, collecting methods, captive maintenance, specimen preservation and snakebite are largely unaltered, although accompanying line drawings have been color tinted and new maps have been provided. Species accounts retain the format of older editions, with sections for description, distribution and habit (readers wanting detailed information on natural history will need to refer to other sources, as only very limited, often superficial data are provided here). Many minor emendations to the accounts have, however, been made, and the accompanying maps for many species have been updated to reflect range extensions and the effects of changes in species concepts. Maps retain the outline ranges used in earlier editions, but the switch from solid black to gray shading permits state boundaries to be seen and thus facilitates orientation. In at least 20 instances, however, the mapped distributions do not closely match the accompanying text or the specimens illustrated are stated to come from localities from outside the ranges as given by the text and/or maps. In a few cases the map nomenclature does not match the text (e.g., on page 677, species currently placed in the genus *Rhinoplocephalus* are mapped as *Unechis* and *Cryptophis*).

Thirty-three new or newly resurrected taxa are included with distribution maps (but no photos) in an appendix, bringing the book up to date at least through early 1991. As in the previous two editions, the species of Australia's Ocean territories are also treated in a separate appendix.

A glossary with more than 240 terms is provided as are general and family references including approximately 625 entries incorporating both broader or more significant systematic and natural history papers, books and monographs, and all papers in which new Australian taxa have been described since 1982. This cutoff allows one to use the reference list as a complement to Cogger et al. (1983), which cites earlier systematic and natural history literature. Many recent papers, especially those dealing with range extensions or the natural history of one or a few species have been omitted, however, and the literature section provided should in no way be construed as a complete overview of the last decade of Australian herpetological research.

Like many systematists, I find myself at odds with Cogger with regard to certain issues, such as the generic allocation of certain species and the recognition of certain names originally proposed in the controversial publications of Wells and Wellington. In these matters, however, the author clearly states that his opinions may differ from others, mentions opposing views, and quite rightly reminds the reader that nomenclature is a fluid reflection of our state of systematic knowledge. A few minor faults, such as the lack of umlauts on German names cited, pagination errors in the literature cited, and the misspelling of scientific names on some photo captions are irksome, but typos are generally few and far between. Although every student of the Australian fauna is likely to have suggestions for some minor improvements, most would agree that errors of omission are as minimal as the magnitude of the task would allow and errors of commission are virtually nonexistent.

Despite the recent release of many fine Australian herpetological books, Cogger's *Reptiles and Amphibians of Australia* remains the essential reference on the fauna of the island continent. The standard established by the latest edition of this work is extraordinary. I regard this book as the single best national (or continental, for that matter) guide to amphibians and reptiles in the world. At nearly $100 this book is still a bargain and should be on the shelves of all general herpetological libraries (although for those who can wait until their next trip to Australia, the version released there is considerably less expensive). The release of the fifth edition of this book is especially timely, coming just one year before the Second World Congress of Herpetology in Adelaide. All delegates who want to maximize their appreciation of the outstanding herpetofauna of Australia should consider this book as required reading.

Encyclopedia of Australian Animals: Frogs, by Michael J. Tyler. 1992. Angus & Robertson, Pymble, N.S.W. ISBN 0-2071-5996-3. 109 pp. $A29.95 (Hardcover).
Encyclopedia of Australian Animals: Reptiles, by Harald Ehmann. 1992. Angus & Robertson, Pymble, N.S.W. ISBN 0-2071-7379-6. 495 pp. $A49.95 (Hardcover).

These volumes contribute further to the impressive record of first-rate herpetological publications by Australian authors, here assisted by the resources of the National Photographic Index of Australian Wildlife to provide nearly complete coverage of Australian frogs and reptiles in a standardized format. Neither book has keys nor often more than cursory descriptions, though the superb photographs can serve in many cases; instead, the emphasis is on natural history information (particularly in Ehmann). Each species account provides one to several paragraphs on biology (Tyler includes descriptions of tadpoles, where known), followed by summary statements of size, habitat, abundance, and status, plus a shaded distribution map. Common names (often new) are provided, as are useful etymologies. Most accounts occupy a half page, and text, photographs, and maps are neatly set together. Genera and families are characterized briefly, often in ecological terms that effectively expand the rationale for recent taxonomic partitioning.

Comparisons with the 5th edition of Cogger's (1992) guide, reviewed above, are inevitable, and may be helpful to those seeking to brush up on the Australian herpetofauna prior to attending the Second World Congress. In general, Tyler's and Ehmann's books complement Cogger very nicely; together with Greer's (1989) excellent volume on lizards and Shine's (1992) masterful treatise on snakes they comprise a minimum reading list on Australian herpetofaunal diversity.

There is close correspondence in nomenclature between Tyler and Cogger; Tyler chooses not to recognize *Metacrinia* and *Paracrinia* as monotypic genera, while retaining *Philoria* as monotypic by delegating three species to *Kyarranus*. A few taxa in the speciose hylid genus *Litoria* are treated differently by Tyler and Cogger, but there is little chance of real confusion arising. Nomenclatural differences are more pronounced between Ehmann and Cogger, particularly in reference to skinks and elapid snakes, and could lead to confusion when trying to use both books. Basically, Ehmann recognizes 30 fewer skink species and 10 more snakes than does Cogger, and he eschews the lizard genera proposed by Wells and Wellington. Thus, Ehmann retains *Phyllodactylus* (for *Christinus* of Cogger), *Leiolopisma* (*Pseudemoia*), *Sphenomorphus* (*Glaphyromorphus*, *Eulamprus* in part), and *Tropidophorus* (*Gnypetoscincus*), and does not separate *Eroticoscincus* from *Nannoscincus*, nor *Saproscincus* from *Lampropholis*. Ehmann also includes *Lucasium* in *Diplodactylus*, and *Lophognathus* in *Amphibolurus*. More confusingly, there is considerable divergence in the use of generic names among elapid snakes. Ehmann recognizes *Cryptophis* and *Glyphodon* for species placed by Cogger in *Rhinoplocephalus* and *Furina*, respectively, and he expands *Denisonia* to include *Suta suta*, and *Elapognathus* to include *Drysdalia* spp. He also incorporates in *Rhinoplocephalus* species placed by Cogger in an expanded genus *Suta*, and retains *Disteira* in *Hydrophis*. Clearly there is still need for agreement on the genera of Australian elapids, if only to help with getting the right antivenom!

Another measure of the maturation of faunal studies can be had from comparisons of contemporary distribution maps; assuming equal care in their compilation and interpolation, these should achieve similarity as the database improves. That this is yet to be achieved for most of Australia west of the Great Dividing Range is evident in the present works. I assessed mapped distributions in Tyler and Ehmann as being essentially the same as given by Cogger, somewhat different, or very different, in the latter instances as being either more or less extensive. For 190 species, Tyler's maps display a normal distribution of variation from Cogger's, scoring 8.4, 23.2, 43.7, 22.6, and 1.6% (from very much less through equal to very much greater). Ehmann's maps are more detailed and more conservative than are Cogger's (scoring 14.3, 27.8, 44.2, 12.5, and 1.1%, n = 622); typically they depict more fragmented distributions, often shown as being slightly more extensive in coastal regions and considerably restricted in the interior of the continent. Based on my field experience in northern and western Australia I feel that Ehmann's maps better represent actual distributions. Some of Ehmann's maps are very different indeed from those in Cogger (e.g., *Ctenotus decanurus, Egernia depressa, Tympanocryptis uniformis*); while it is sometimes evident that a name is being applied to different animals (e.g., *Egernia richardi*), in most cases the departures reflect a familiarity with outlying records and detailed knowledge of the species' requirements and the terrain on Ehmann's part.

The photographs are a primary feature of both volumes of the Encyclopedia, representing the best efforts of dozens of individual contributors to the ambitious Index project. If an Australian frog or reptile has ever been photographed alive, it is likely to be represented. Tyler illustrates all but 7 of 197 species of frogs, including 26 not figured by Cogger. In general photographs in Tyler are sharp and well cropped, and usually somewhat larger than those in Cogger, although the latter often illustrates individual variation, and where appropriate shows diagnostic features of the ventral coloration. Ehmann figures all but 32 species of reptiles (including 11 typhlopids for which line drawings of head scalation are provided, and 9 hydrophiids), compared to 129 species which are not illustrated by Cogger (who does depict 6 species not shown in Ehmann). Nearly half of the photographs in Ehmann are the work of the author, and with the exception of poor prints of *Ephalophis greyi* and *Hydrelaps darwiniensis* they are of excellent quality. A few photographs are poorly cropped or are inexplicably reproduced at less than the usual size, but overall the illustrations alone are well worth the modest price of either volume.

While Tyler provides some information on natural history for virtually every Australian frog, Ehmann's book contains a real wealth of such material, in my view rendering it far more than simply an illustrated compendium. Nearly every account has new information, much of it identified as being based on personal observation. Ehmann has clearly sought to understand distributions in ecological terms, drawing in soils, topography and prey ecologies as well as the standard climatic and vegetational descriptors. He presents literally hundreds of fascinating insights that could serve as a guide to much of the next generation of research on the biology of Australian reptiles. These notes and comments would be invaluable for any fauna, but are especially meritorious in the Australian context, where precious few sources can or do provide much information on basic natural history.

Tyler and Ehmann can rightly be proud of these careful contributions, which do credit to the Encyclopedia. The volumes are virtually free of typographic errors, and are well assembled and securely bound, enough so to withstand the repeated reference they deserve. Both books should be on the shelves of anyone interested in the Australian fauna; students of reptile behavior and ecology could also profit from a close reading of Ehmann's insightful species accounts.

Venomous Reptiles of North America, by Carl H. Ernst. 1992. Smithsonian Institution Press, 470 L'Enfant Plaza, Suite 7100, Washington, D.C. 20560. 236 pp. Hardcover. $35.00 U.S. ISBN: 1-56098-1148.

In this book, Ernst sets for himself the formidable goal of reviewing the natural history of the venomous reptiles of North America. This task proves to be a double-edged sword. The reader is offered a truly impressive amount of detailed, current information which is, for the most part, well organized and presented. This same emphasis on detail, however, results in some stylistic limitations.

The author is careful to explain his restriction of the book's scope to natural history, or "the life of the reptile in the wild." Accordingly, papers on morphology, physiology, biochemistry, and other "technical papers" are excluded. With the possible exception of the taxonomic and phylogenetic relevance of crotalid vertebral morphology, which the author discusses without ever describing the vertebrae, these exclusions do not detract from the work. Venom is discussed only in terms of yield and toxicity; venom biochemistry is described only when several distinct venom "morphs" occur, as with *Crotalus scutulatus*.

The book covers the Gila monster, *Heloderma suspectum*; the sea snake *Pelamis platurus*; the coral snakes (*Micruroides euryxanthus* and *Micrurus fulvius*); and the 17 species of North American crotalids. For each species the author summarizes information on the following topics: recognition, karyotype, fossil record, distribution (supplemented with generalized distribution maps), geographic variation, confusing species, habitat, behavior, reproduction, growth and longevity, food and feeding, venom and bites, predators and defense, populations, and "remarks" which normally focus on presumed relationships. The length of the species accounts varies considerably (from three pages for the twin-spotted rattlesnake, *C. pricei*, to 20 pages for the western rattlesnake, *C. viridis*) depending on the number of subspecies discussed and the extent of our knowledge of the species' natural history.

The illustrations are one of the weakest points of the book. There are 33 black-and-white illustrations. Several species are not covered by these, and many of the figures included do not clearly demonstrate the characteristic features of the species. Line drawings of the scalation patterns, or close up photographs of the heads would have been useful. An additional 55 color plates illustrate each species discussed, and many of these are both informative and aesthetically pleasing. A reasonable number, however, are washed-out, and many depict the snakes upon artificial backgrounds that seem inappropriate for a book devoted to natural history. Overall, the information content of the illustrations is less than it should have been. For example, nowhere are the characteristic supraocular "horns" of *C. cerastes* clearly illustrated.

The book is well written, and the number of typographical errors is fairly low. There are a few noticeable errors and omissions. When discussing the defensive musk of the copperhead, a typo leaves the author seemingly in agreement with the folktale claim of an aroma like cucumbers; in the subsequent account of the cottonmouth no mention is made of a defensive musk, although this behavior has been previously described (Burkett 1966). In some instances, especially when detailing predators, the lack of citations leaves it unclear if the information presented is simply the opinion of the author.

It would have been of benefit to have some of the detail presented in the individual species accounts put into a broader context in a generalized introduction or conclusion. The author is certainly capable of providing this information; but the introduction to the Viperidae is very brief (and focuses mainly on the pit organ), and the general introduction only touches on selected points. Throughout the species accounts of the rattlesnakes, the author discusses previous phylogenetic studies. Three of these, using morphology, venom biochemistry, and scale microdermatoglyphics yielded contradictory results, yet nowhere are the results of these studies summarized. The index, consisting almost exclusively of the scientific names of the snakes discussed, is far too brief for the amount of information in the book. As such, a reader wanting to know which snakes are preyed upon by raccoons is forced to read the "predators and defense" section of each species account.

While these difficulties detract from the book, they in no way minimize its value. This book does not have the easy-page-turning style that one finds in works like Shine's *Australian Snakes: A Natural History*, but it was not intended to. What the book does is provide a wonderful resource to workers wanting detailed, current information on the natural history of these snakes. The species accounts cover some 160 pages of generously spaced text; these are supported by a 50-page bibliography! The vast majority of the papers cited in the bibliography are recent works, since the author uses the bench-mark works of Wright and Wright (1957) and Klauber (1972) to reference the older literature.

Ernst's book will be of considerable value to anyone interested in the natural history of the venomous reptiles of North America, and given the relatively modest price of this work, it will undoubtedly find a broad audience.

Snakes of the United States and Canada: Keeping Them Healthy. Volume 1. Eastern Area, by John V. Rossi. 1992. Krieger Publishing Company, Malabar, Florida. xiii + 209 pp. 100 color plates, 17 b/w photographs, 43 maps. Clothbound. ISBN 0-89466-590-0. $42.50 U.S.

The explosion of herpetoculture over the past fifteen years or so has led to a consequent rise in the number of titles addressing the captive husbandry of amphibians and reptiles (e.g., Mattison 1982, 1988; Mehrtens 1987; Ross and Marzec 1990). The present volume is the latest contribution to this growing list.

Rossi's work is divided into four sections which address general care, individual species accounts, venomous snakes, and "disasters." Each section is further divided to address a number of other topics. For example, in the general care section housing, temperature requirements, cleanliness, lighting, food, behavior, hibernation, egg incubation, and diseases are discussed. Species care is a section comprised of individual species accounts with specific recommendations and guidelines for each taxon. The venomous snake section is a composite of general observations and comments and individual species accounts. The disasters section includes anecdotal accounts of actual or potential problem areas in husbandry that the author has encountered. The accounts are obviously intended to alert the reader to similar problems with their animals. Additionally, the four sections are followed by appendices for professional and regional herpetological societies and references, an index of common names, and a subject index.

The general care section addresses most of the basics of the captive maintenance of snakes. I was impressed that the author recommends a standard quarantine period for new arrivals to a live collection. Although quarantine periods are standard procedure for zoos and other institutions that maintain live snakes, this practice is rare in private collections. Further, Rossi stresses consistent disinfection technique, another practice that is frequently neglected. This is an area than cannot be overemphasized as many of the ills of captive snakes can be directly traced to poor disinfection procedures. Cleanliness *is* godliness in captive snake husbandry.

The individual species accounts cover 51 taxa. Although the title implies that taxa covered are from the eastern half of the United States and Canada, it is apparent that only forms from east of the Mississippi River are covered. With the exception of *Lampropeltis t. triangulum* and *L. t. elapsoides*, only forms at the species level are addressed. Each species account includes information on captive care and breeding and each has a boxed capsule summary of important care factors and a range map. It is obvious that Rossi has had considerable experience with the majority of forms covered. He offers some unique insights into the husbandry of many of the smaller, more secretive snakes found in this area. The husbandry requirements of such snakes merit more investigation than is currently occurring and I applaud Rossi for dealing with many of these species in detail.

Dr. Rossi has certainly engaged in an ambitious project (with the implication that an additional volume or volumes will follow). Unfortunately, this first work does not bode well for future volumes, if the current style, editing, and content are retained. The problems with this book are many and occur throughout the book.

My primary complaint lies with editing and copy editing, or rather, the lack thereof. Although Rossi attempts a conversational style of writing, poor editing has contributed to many examples of tortured phrasing that limit the author's ability to get his point across. The following are a few examples: "As ectotherms, animals which derive the majority of their body heat from outside the body, (formerly known as cold blooded animals,...);" "watch out if you are using pegboard as it will sometimes trap too much moisture and make the cage very damp. This restricts ventilation, and thereby increases humidity because evaporated water is trapped. Many professional herpetologists keep a humidifier running in their snake rooms throughout the winter...to avoid these problems;" "It only takes one lucky shot for a mouse to nail a snake in an eye or inside of the mouth." The image that comes to mind for the latter sentence, a terrified mouse with a gun, is, I am sure, not what Rossi intended. Additional examples of poor editing are found in irritating switches between lowercase and capitalized common names throughout the book (sometimes in the same sentence), non-use of hyphens (metal rimmed, wild caught, five lined, etc.) throughout, misspellings ("*getulua*" instead of "*getula*", "excatly" instead of "exactly", "*Storiea*" instead of "*Storeria*", "discalium" instead of "dicalcium", etc.), and another irritating trend of allowing the author to refer to species accounts several pages ahead, thereby forcing the reader to flip ahead to that section, read to what Rossi is referring, then return to the previous account. All of these errors, in addition to certain factual ones and misleading statements by the author, make this book a very difficult read for knowledgeable herpetoculturists.

Also, I have a number of disagreements as to statements of fact, misleading statements, and philosophy. The most worrisome to me is the idea—promoted by Rossi—that the only hope for the continued survival of snakes is through captive breeding. As he states in his preface, "But with the massive global habitat destruction going on now, the more people that [*sic*] are exposed to these creatures, the better off these animals will be in the future when the experience and awareness we gain now will result in the production of captive bred snakes. In the not too distant future captive snakes may be the only snakes!" Although Rossi is certainly correct in determining the major cause of certain snake declines, captive breeding is not and will not be the answer to protecting endangered taxa. In rare cases, well-conceived and well-managed captive breeding programs may serve as a useful adjunct to preservation and conservation of such species. However, the sort of willy-nilly approach that the author appears to advocate is, to me, virtually useless for conservation purposes. Indeed, it is dangerous to imply a degree of impending extinctions that is totally false. This is environmental alarmism at its worst and it affects other sections of the book.

For example, Rossi has included a very disturbing section titled "Releasing Snakes." He directly encourages the deliberate release of captives into wild populations, ostensibly for the purpose of augmenting those populations. This is incredibly naive at best, and dangerous at worst. As I have outlined previously (Rundquist 1978), the state of our knowledge regarding deliberate introduction of exotic taxa (and this includes individuals from other populations of a species) and the effects on native forms is still too meager to advocate any such tinkering. The risk of unknown and unknowable genetic effects is great as are the baffling possibilities presented to population geneticists and others studying interpopulational variation should these specimens appear in the course of their studies.

Further, the possibility of introducing pathogens to populations unequipped to deal with them is also large. The upper respiratory syndrome that has caused such concern to those working with desert tortoises (*Gopherus agassizii*) in the southwestern U.S. now appears to have surfaced in gopher tortoises (*G. polyphemus*) in the southeastern U.S. and most likely was introduced there from captive desert tortoises or other captives exposed to this disease. The potential for snakes is the same, particularly with such devastating illnesses as paramyxovirus. Rossi states his justification for release as follows: "Theoretically, since most of their behaviors are instinctive rather than learned (at least at first), there should be few problems for healthy snakes to adjust." How much of *any* snake's behavioral repertoire is instinctive or learned is unknown at this time and it is extremely dangerous to promote any sort of release until all parameters for a species' survival are understood. What little information is available suggests that survivorship of released captives is very poor (D. Chiszar, pers. comm.).

This conservation via captive breeding theme also is evident in several species accounts. Rossi states in the indigo snake account that "of the thousands of snakes that were present at the first National Breeders' Expo..., there were no Indigos because of strict over regulation," as if captive breeding would have solved the problem of habitat destruction for this species. There were no *Drymarchon* at this gathering because the snake is federally and state protected, not over regulated. That protection has helped preserve the remaining wild populations, to which unorganized captive breeding would make *no* contribution.

There are many other problems with this book that, unfortunately, I do not have the space to address. Suffice to say that I cannot recommend it, particularly at the high price at which it is being marketed. Krieger and Rossi would be well-advised, though, in future volumes to pay much closer attention to basic editing and to have the various sections reviewed by knowledgeable herpetoculturists and herpetologists prior to publication.

PUBLICATIONS RECEIVED

Sea Snakes, by Sneed B. Collard III, illustrated by John Rice. 1993. 32 pp. Hardcover. Bell Books, Boyds Mills Press, Honesdale, Pennsylvania. Distributed by St. Martin's Press.

This is a book for young readers desiring basic biological information about sea snakes. The book is illustrated both with color drawings and underwater photographs of mostly good quality. Much of the text is devoted to dispelling certain myths about sea snakes or informing the reader of some of the more fascinating aspects of sea snake natural history, such as their geographic distribution, diving ability, venoms, salt excretion, locomotion, commercial use, and reproduction. A seven-year old budding herpetologist's reaction: "I like it a lot; I learned a lot I didn't know."

Altitudinal Ecology of *Agama tuberculata* Gray in the Western Himalayas, by Robert C. Waltner. 1991. The University of Kansas Museum of Natural History Miscellaneous Publication No. 83. 74 pp. Softcover. $5.00 US.

A comparison of the ecology of low (690 m) and high (2165 m) altitude populations of *Agama tuberculata* in northern India. Parameters considered include morphology, growth, diet, activity, temperature relations, reproduction, survivorship, and biomass. In addition to providing altitudinal comparisons, this study is significant in that it represents one of relatively few detailed autecological studies on Asian agamid lizards.

Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986-1992, et. seq. Privately published by and available from the author (Ralph W. Axtell, 2814 Rock Hill Road, East Alton, Illinois 62024, USA). Individual accounts available separately.

Twelve accounts, issued at irregular intervals and totalling 212 pages, have been published to date. Species covered thus far are *Coleonyx brevis, Sceloporus cyanogenys, S. p. poinsettii, S. graciosus arenicolus, S. variabilis marmoratus, S. grammicus disparilis, S. olivaceus, S. magister, Phrynosoma modestum, Crotaphytus collaris, C. reticulatus*, and *Cophosaurus texanus*. Accounts range from four pages for *Sceloporus graciosus arenicolus* to 42 pages for *Sceloporus olivaceus*. The accounts include the author's interpretation of Texas distribution, dispersal mode and distributional status (whether contracting, expanding, or static), population density, elevational range, doubtful or unnatural records, extinct or extirpation prone populations, potential records, reptiles with similar distributions, and suggestions for future work. Voucher records from most U.S. museums and collections are listed by county. The format is 8.5 x 11-inch looseleaf pages that are three-hole punched for easy placement into a binder. Detailed dot maps (in color) with hypothetical range limits are provided for each species.

ERRATA

In the note by Luke J. Thirkhill and Bryan L. Starrett reporting a range extension for *Crotalus willardi* (HR 23(4):124), the authors' address should read P.O. Box 9043, Scottsdale, Arizona 85252, USA.

In the note by Sazima et al. (HR 23(4):120-121), the generic name of the snake involved was consistently misspelled due to a typesetting error. The correct spelling is *Rhadinaea bilineata*.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address). ***HR*** especially encourages the submission of articles of broad interest to the herpetological community.

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information, including correct format for literature citations. More detailed information for submissions to Geographic Distribution, Life History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings.

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints.

For further guidelines, authors should consult the *CBE Style Manual* (5th edition, 1983, Council of Biology Editors, Inc., 9650 Rockville Pike, Bethesda, Maryland 20814, USA).

Submissions for Life History Notes, Geographic Distribution, Herpetological Husbandry, Recent Population Changes, Regional Society News, and Legislation & Conservation Alert should be sent directly to the appropriate section editor (see inside front cover for names and addresses). Review copies of books should be sent to the Book Review Section Editor (name and address on inside front cover). Manuscripts intended for publication as Feature Articles, Techniques Articles, Points of View, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes, and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. At present, there is little lag time between acceptance of a manuscript and its publication. Although the advice and assistance of three reviewers will be sought for all feature articles, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Life History Notes ordinarily will be reviewed by the Section Editor only. The Editor and Section Editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints of notes or articles published in ***HR*** cannot be supplied. Authors may reproduce up to 200 copies of pages containing their articles for private distribution only. Reproduction for sale purposes is not permitted.

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Advertising Manager (see inside front cover for address). Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats; contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

RWH

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc. RFD 6 Box 1, Lawrence, Kansas 66046. *Herpetological Review* is composed using Microsoft Word and Aldus Pagemaker on Apple Macintosh computers. Camera-ready copy is produced on a Linotronic 230 Imagesetter at a resolution of 1700 dpi at Valley Type & Design, Fresno, California. All rights reserved. No part of this periodical may be reproduced without written permission of the editor.

SOCIETY FOR THE STUDY OF AMPHIBANS AND REPTILES

NEW PRICE for the

Catalogue Of American Amphibians And Reptiles

The catalogue consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere.

COMPLETE SET: NUMBERS 1 - 530	$200.00
INDEX TO ACCOUNTS 1 - 400: Cross-referenced, 64 pages	$5.00
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$5.00
IMPRINTED POST BINDER: (note - two binders are needed for the 505 accounts)	$25.00
INCOMPLETE SET: NUMBERS 1 - 190	$60.00
191 - 410	$70.00
411 - 530	$75.00

Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, check on a US bank, or by Mastercard or Visa (include account numbers and expiration date of credit card). Subscriptions to ***Herpetological Review only are available for $12.00 annually. Subscribers to ***HR*** only are not members of the Society. ***Catalogue of American Amphibians and Reptiles***: subscription is $15.00 annually ($3.00 air delivery surcharge if airmail is desired.). Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

INSTITUTIONAL PROFILE

Herpetology At Indiana University

Indiana University at Bloomington is located 40 miles south of Indianapolis. Much of the surrounding countryside is forested. The 2000-acre campus is heavily wooded and is often regarded as among the most beautiful in America. IU is the oldest state-established university west of the Allegheny Mountains, founded at Bloomington in 1820. It now serves nearly 94,000 students on eight campuses. The residential campus at Bloomington and the urban center campus at Indianapolis form its core. With 853 degree programs, the university attracts students from all 50 states and around the world.

The first natural historian on the faculty was Richard Owen who was followed on the faculty by the ichthyologist David Starr Jordan. Jordan eventually became president of Indiana University and later, Stanford. Jordan Hall (which houses the Department of Biology), Jordan Avenue, and IU's Jordan "River" are all named for him. Jordan was succeeded as head of Zoology by his collaborator in ichthyological explorations, Carl H. Eigenmann. Biologists played a key role in the development of the graduate programs at IU. Eigenmann became the first dean of the Graduate School. The second and fourth deans were geneticists Fernandus Payne and Ralph Cleland. Today the Graduate School awards approximately 300 Ph.D.'s and 500 master's degrees annually.

Some studies of local amphibians were carried out by Will Scott (an aquatic biologist) and Frank Young (an entomologist) and their students. The first faculty member hired who worked primarily with reptiles or amphibians was the embryologist Robert W. Briggs, famous for his work on amphibian development. He attracted as a coworker Rufus R. Humphrey who had retired from the University of Buffalo. Humphrey brought with him his colony of axolotls and worked at IU until his death in 1977. The axolotl colony continues under the direction of George Malacinski and is a major resource for studies in developmental genetics, both at IU and elsewhere.

Facilities

A number of university facilities and nearby resources are particularly attractive for students with interests in field research with amphibians and reptiles. These include a 300-acre woodland tract on the shore of Lake Monroe and the 90-acre Kent Farm research area. Moreover, southern Indiana contains a very large concentration of state parks and state and national forests. The Crane Naval Reserve alone includes 100 square miles of potential research sites and is well protected from public access (the periphery is patrolled by military police with attack dogs). Research facilities also include extensive animal quarters (including axolotl and turtle colonies and rooms for individual research projects), sophisticated molecular biology and microscopy installations, and a major computer facility .

IU's Library collections are among the 20 largest in the country. The Biology Library maintains approximately 1200 current journal subscriptions and includes some 95,000 volumes.

The Medical Sciences Library has 269 serials and 7500 volumes. Additional relevant materials are in several other libraries. On-line and CD-ROM literature searches are easily done. The Lilly Library of rare books contains many scarce herpetological classics, especially from early work in Latin America, as well as first editions of many classic items, including Darwin's *On the Origin of Species.*

Programs

Most of the students who are interested in herpetology work in the Evolution, Ecology, and Behavior Programs (EEB) in the Department of Biology. The Ph.D. and M.A. degrees in EEB can be obtained in the areas of ecology, population biology, or evolutionary biology. The 20 EEB faculty are engaged in research ranging from ecosystem, community function, and population biology to physiological ecology, plant systematics, and evolutionary genetics. There is an especially strong interdepartmental program in animal behavior.

FIG. 1. White River in Bartholomew County, Indiana. Seven species of turtles occur here. Photograph by Michael A. Ewert.

Research Programs

Robert Devoe (Optometry) studies motion detection by cells in the turtle retina. He uses intracellular recording and staining to measure responses to moving patterns and to identify the cells anatomically. He finds that about 34% of all cells recorded respond best to motion in a certain direction and much less well to motion in the opposite direction.

Michael A. Ewert (Biology) employs a comparative approach to his studies of development of reptilian (mostly turtle) eggs. He is most interested in ecological and evolutionary perspectives, especially as concerns developmental rate, correlates of energy expenditure, and environmental sex determination.

George Malacinski (Biology) studies the genetics and molecular embryology of early amphibian development. His research focuses on the establishment of egg polarity and its relationship to buoyant density differences in egg cytoplasm components, on the development of mesoderm differentiation, and on axolotl developmental genetics.

Anthony L. Mescher (Physiology) is interested in tissue interactions during development, especially amphibian limb regeneration. Currently he is investigating the hypothesis that nerves release transferrin and that this may be involved in the neural stimulation of regeneration in the amphibian limb.

Anton W. Neff (Physiology) is interested in the establishment of primary early embryonic patterns in vertebrates. He uses amphib-

ian embryos in his studies of the role of the egg cytoplasm and cytoskeleton in the establishment of dorsal-ventral polarity, of somitogenesis and the differentiation of myotomes, and of cardiogenesis.

Craig E. Nelson (Biology) is interested in evolutionary ecology, especially of amphibians and reptiles. Current and recent projects in his group focus on the adaptive nature of sex-determination in reptiles, on reptilian reproductive strategies, on mate choice by female frogs, and on the efforts of temporal and spatial heterogeneity on the structure of pond-breeding amphibian communities.

FIG. 2. Ledges along Sugar Creek in Park County. Many species of amphibians and reptiles are found in the rock outcrops that are common in southern Indiana. Photograph by Michael A. Ewert.

Paul Pietsch (Optometry) uses larval salamanders (genus *Ambystoma*) to make experimental inquiries into the biological basis for memory, perception and learning. Currently, and in collaboration with Carl Schneider of the Psychology Department of Indiana University of Pennsylvania, he is trying to find out how experimental alterations (e.g., eye transplants) in the visual system affect the larvae's visually evoked behavior.

John B. Phillips (Biology) studies the sensory specializations underlying behavior. Among his current foci are the sensory mechanisms underlying magnetic field and polarized light detection; the sensory basis of navigation and dispersal in vertebrates; and sexual selection and the evolution of mating systems. Much of his current work is with salamanders and turtles.

Henry D. Prange (Physiology) studies temperature regulation in reptiles and other animals, the respiratory physiology of hypoxia in axolotls and other bimodal breathers, and respiration of eggs and its relationships to sex determination in turtles.

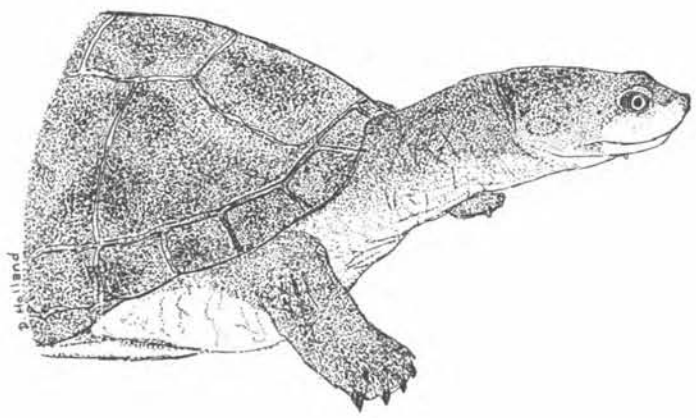
William J. Rowland's (Biology) work combines ethological, ecological, and evolutionary approaches to investigate behavior. His work has focused especially on communication and reproductive behavior of fishes, mainly sticklebacks. His group has also addressed these questions in salamanders and lizards.

Dolores M. Schroeder (Physiology) studies structure-function relationships of the central nervous system by examining variations across a wide range of vertebrates. Her current focus is on the intrinsic mechanoreceptor of the spinal cord.

Barry Sinervo (Biology) is currently working on two related lizard life history problems that involve maternal investment: optimal offspring size and costs of reproduction arising from levels of maternal investment. He has developed several experimental manipulations (allometric engineering) of maternal investment per offspring and total investment that permit a causal analysis of natural selection on these traits in the wild. He has used these techniques on a wide range of size-related evolutionary problems that involve reptiles.

Fort Wayne Program

The Indiana University program at Fort Wayne, Indiana, is shared with Purdue University. IUPUFW offers a master's degree in biological science. Moreover faculty there usually have graduate-faculty status in the Indiana University system and can thus direct dissertations and serve on graduate committees for students working in Bloomington. IUPUFW facilities include the Crooked Lake Research Station and an animal care facility with good environmental controls and a staff already accustomed to caring for reptiles. Several faculty have strong herpetological research interests:



William E. Cooper (Biological Sciences) is interested in the behavioral ecology of squamates with special interests in both proximate and ultimate factors affecting social behavior, feeding, and defense. Currently he is working on the use of chemical cues in foraging behavior and pheromonal communication, and on the influence of foraging mode on the use of tongue-flicking to identify prey chemicals. He also studies female reproductive coloration, sexual selection, and comparative aspects of the foraging mode.

James O. Farlow's (Geosciences) research interest is dinosaur biology, especially the reconstruction of behavior and ecology. He studies the behavioral implications of dinosaur tracks and tooth structure and the relationships among body size, body temperature, and behavior.

Bruce A. Kingsbury (Biological Sciences) is interested in the physiological ecology of temperature regulation in alligator lizards, activity cycles, and habitat selection in lizards and turtles. He is currently doing field studies of foraging behavior in tropical gekkonid, phrynosomatid, and teiid lizards.

Frank V. Paladino (Biological Sciences) studies the physiological ecology of sea turtles with emphasis on temperature regulation, diving, and reproductive biology. He currently works with nesting and migration in leatherback turtles in Costa Rica.

CRAIG E. NELSON
Department of Biology
Indiana University
Bloomington, Indiana 47405, USA.

SSAR Meeting Highlights

Dates: 7–12 August 1993
Place: Indiana University, Bloomington, Indiana

Keynote Lecture: "Feeding Strategies of Monitor Lizards," by Walter Auffenberg (Florida State Museum). An in-depth, illustrated lecture on the behavior and ecology of the Komodo, Gray's, and Bengal monitors.

Symposium: "Reptilian Behavioral Ecology: A Tribute to Charles C. Carpenter." *Organizers*: James Gillingham and Thomas Jenssen. *Participants*: Robin Andrews, Gordon Burghardt, Geoffrey Carpenter, David Chiszar, William Cooper, Justin Congdon, David Duvall, Gary Ferguson, Neil Ford, Brent Graves, Neil Greenberg, Victor Hutchison, Beth Leuck, Jeffrey E. Lovich, James B. Murphy, Catherine Marler, Joseph Macedonia, Matthew Rand, Stephen Secor, Judy Stamps, Richard Tokarz, and Kent Vliet.

Symposium: "Vision and Visual Cues in the Behavior of Amphibians and Reptiles." *Organizers*: Richard King and John B. Phillips. List of Speakers not yet finalized.

Herpetological Travelogue Slide Shows: Aaron Bauer (Australia, New Zealand, and New Caledonia), Stephen D. Busack (Spain), Thomas Fritts (Galapagos Islands), and C. J. McCoy (Belize). 30-minute, profusely illustrated lectures.

Oral and Poster Presentations: Several concurrent sessions each day. Abstract form in *Herpetological Review*, December 1992 issue, page 97.

Student Paper Awards: Seibert Prizes to be awarded to the two best student papers ($250 first prize, $150 second prize).

"The Great Reprint Scavenge." (For Students Only!). Professionals are asked to clear unwanted duplicate reprints out of their offices (and get free raffle tickets as a "thank you"). Only students will be permitted to sort through the stacks.

Audiovisual Shows: "Herps of the West" (newly updated), "Amphibians of the Appalachians" (updated 1992), and "Herpetology Past and Present."

Field Trips: "Herping with Joe Collins."

Social Activities: Welcoming Reception, the Annual SSAR Auction, Gourmet Beverage Tasting, local tours, and raffle.

Exhibit: Tour of the Indiana University Axolotl Facility, a national facility founded by R. R. Humphrey that breeds and maintains genetic stocks of axolotls for research and teaching.

Live Exhibit: Herps of the Region (Sponsored by the Hoosier Herpetological Society).

Costs: Registration: $50 student, $70 regular; after 15 June, $70 student, $95 regular. Lodging at Indiana University Union (meeting site): $55/day (single) to $88/day (4 persons/2 beds). Air-conditioned dorms are $18/day (double occupancy) and $23.50/day (single occupancy).

Further Details, Call for Papers, and Abstract Form: See the December 1992 issue of *Herpetological Review* (page 97) or on request from Craig E. Nelson, Department of Biology, Indiana University, Bloomington, Indiana 47405 (telephone 812-855-1345, fax 812-855-6705).

SSAR BUSINESS

SSAR Election Results

Results of the recent SSAR election are as follows:

President-elect (to serve as President for 1994): Lynne D. Houck.

Secretary: J. Eric Juterbock (unopposed).

Treasurer: Douglas H. Taylor (unopposed).

Directors: David M. Green, Gregory K. Pregill.

Proposed Amendments To Bylaws

Two amendments to the SSAR bylaws are to be discussed at the 1993 Annual Meeting in Bloomington, Indiana, 7-12 August. In each case, the current wording needing amendment is printed with an overstrike, and the suggested replacement follows in brackets.

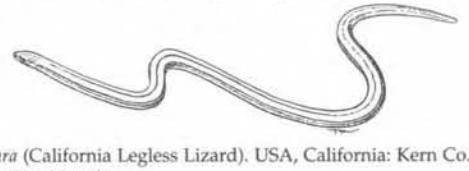
The first involves the list of and the duties of appointed officers, and the amendment will allow the needs of the Society to conform strictly to the Bylaws.

Article II. Section 1. b.

The appointed officers shall include an Editor of the official journal, an Editor of the Society Newsletter, ~~an Editor of miscellaneous publications~~ [Editors of other publications, as deemed necessary by the Board], and a Publications Secretary.

Article II. Section 6. c.

The ~~Editor of the miscellaneous~~ [Editors of the other] publications shall be responsible for all phases of the publication of monographs, facsimiles, and such special publications as may be issued by the Society. The ~~Editor is~~ [Editors are] responsible to the Board of Directors, to whom annual reports are made.



The second proposed amendment involves the timing of the return of ballots for both the annual election and the amendment of the Constitution and Bylaws; the amendment will clarify the date by which ballots must be returned.

Article IV. Section 4.

The Slate of Nominations shall be prepared in ballot form and circulated to the entire membership by the Secretary not later than one month after the annual meeting. Ballots, to be valid, must be returned to the designated recipient ~~within a three-week period of the~~ [by the due] date printed on the ballot.

Article IX. Section 4.

Within one month after the meeting the Secretary shall send a ballot on amendments to the entire membership. To be valid the marked ballots shall be returned to the Secretary ~~within a three-week period of the~~ [by the due] date printed on the ballot.

Anniella pulchra (California Legless Lizard). USA, California: Kern Co., Oiler Cyn. Illustration by Tim Manolis.

SSAR SEEKS NEW TREASURER

After six years as Treasurer, Doug Taylor has announced his retirement and the Society is seeking a replacement. The Treasurer is one of the critical officers in SSAR and, historically, has been intimately involved in innovative changes in the Society's programs. As such, this person is in a key position to influence the development of SSAR and of the herpetological community.

The Treasurer is responsible for planning the annual budget (currently about $175,000), for maintaining the membership list, and for handling all funds (dues payments, disbursements). The office has its own substantial budget, including funds for a part-time assistant and the purchase of computer equipment.

Interested persons should contact the chair of the Search Committee, Dr. Edward Moll, Department of Zoology, Eastern Illinois University, Charleston, Illinois 61920 (phone: area 217, 581-5410 office).

All inquiries will be held in strict confidence.

Illustrations Wanted For *HR*

The editorial staff is looking for high quality illustrations of herpetological subjects for possible publication in *Herpetological Review*. Original drawings should be of a scale that would permit reduction to approximately 30 x 90 mm or smaller. Of particular interest are drawings of material for which locality data or museum catalogue numbers are available; this information should be included with the drawings. Original art (or photocopies) should be packaged to ensure safe delivery and sent to the Editor (address on inside front cover).

Thanks To Reviewers

The Editor and the Society acknowledge, with considerable appreciation, the assistance of the following individuals in evaluating manuscripts for *Herpetological Review* during 1991-92. An * indicates consultation on two or more manuscripts.

Marsha Anderson*, Royce Ballinger, Aaron M. Bauer*, Joseph Beatty, H. Bernard Bechtel, Robert Bezy*, Karen Bjorndal, Bayard Brattstrom, David R. Breinenger, William S. Brown, Russell L. Burke, Bruce Bury, Stephen D. Busack, Jonathan Campbell, Charles Carpenter, Gustavo Casas-Andreu, Dennis L. Claussen, Joseph T. Collins, Roger Conant, P. Stephen Corn, Kevin de Queiroz, Joan Diemer, James R. Dixon*, William E. Duellman, Harold Dundee*, Karen Lind Eckert, Scott Eckert, Carl Ernst*, Gary Fellers, Gary Ferguson, John Ferner, Harvey Fischer, Richard Franz, Thomas Fritts, Darrel Frost*, Fredric L. Frye, David A. Galbraith, David Germano, James Gillingham, Steve Godley, Stephen Goldberg, David Good, Stefan Gorzula, Terry Graham*, Bruce Grant, Harry Greene*, L. Lee Grismer, Paul Gritis, Louis Guillette, Craig Guyer, James Hanken, James Harding, David Hardy, Laurence M. Hardy, Marc Hayes, Jean-Marc Hero, Bob Herrington, John Iverson, Elliott R. Jacobsen, W. Bryan Jennings, Jeff Howland, J. Eric Juterbock, Robert Kaplan, Kenneth Kardong, Daryl Karns*, Arnold Kluge*, James N. Layne, Howard Lawler, James D. Lazell, Harvey Lillywhite, Ernest A. Liner, Jeffrey Lovich, Douglas Mader, William Mautz, Roy McDiarmid*, Laurie McDonald, George Mid-

dendorf, Sherman Minton*, Joseph Mitchell, Richard Montanucci*, Steve Morey, James Murphy*, Christopher Pague, George Pisani, Michael V. Plummer, Gregory Pregill, William Presch, Peter Pritchard, A. Stanley Rand, Martin Raphael, Steve Reichling, Howard Reinert*, Robert Reynolds, Mark E. Ritke, Douglas A. Rossman, Jay Savage*, Greg Schneider, Allen Schoenherr, Gordon Schuett, Norm Scott, Stephen Secor, Michael Seidel, John Simmons, Glenn Stewart, Stephen Tilley, C. Richard Tracy, Tony Tucker, R. Wayne Van Devender, Thomas R. Van Devender, Jens Vindum*, Laurie Vitt, Marvalee Wake, Dawn Wilson, John W. Wright*.

NEWSNOTES

Request For Nominations World Congress Of Herpetology

During the Second World Congress of Herpetology, to be held in Adelaide, Australia between 29 December 1993 and 6 January1994, half of the members of the Executive Committee and half of the members of the International Herpetological Committee will retire. Membership to both these committees is open to all herpetologists and should be as representative as possible of herpetological subdisciplines and the geographic distribution of herpetologists. Retiring members are eligible for re-election.

Nominations to fill the vacancies can be taken now until 29 August 1993. Nominations must be seconded either by any two members of either the Executive or International Herpetological Committees, or, in the case of the International Herpetological Committee, by the governing body of an Affiliated Organization. Where the number of nominations exceeds the number of vacancies then the election will be by open ballot (during the business meeting) of a format to be determined by the Executive Committee.

Present Executive Committee members (with asterisk retiring at SWCH): R. Avery, UK; W. Böhme, Germany; *D. G. Broadley, Zimbabwe; *R. L. Carroll, Canada (Treasurer); *G. Casas-Andreu, México; *H. G. Cogger, Australia; *J. C. Daniel, India; *I. S. Darevsky, Russia; W. E. Duellman, USA; T. R. Halliday, UK; *M. S. Hoogmoed, Netherlands (Secretary-General); K. Klemmer, Germany; *M. R. K. Lambert, UK; J. Lescure, France; J. M. Savage, USA; *P. E. Vanzolini, Brazil; M. H. Wake, USA; Y. L. Werner, Israel; R. Whitaker, India; *E. Zhao, China.

Present International Herpetological Committee members: R. A. Acuña Mesen, Costa Rica; P. Alberch, Spain; *J. -L. Amiet, Cameroon; N. Ananjeva, Russia; C. Andrén, Sweden; *H. Arnold, UK; A. M. Báez, Argentina; *I. Baran, Turkey; *W. Beçak, Brazil; *B. D. Bell, New Zealand; L. J. Borkin, Russia; S. D. Bradshaw, Australia; *W. R. Branch, South Africa; *E. R. Brygoo, France; J. Castanet, France; C. H. Daugherty, New Zealand; *A. Dubois, France; *J. R. Formas, Chile; D. R. Frost, USA; *C. Gans, USA; D. M. Green, Canada; *H. Heatwole, USA; *R. E. Honegger, Switzerland; *R. F. Inger, USA; U. Joger, Germany; *R. F. Laurent, Argentina; *M. J. Littlejohn, Australia; *S. H. Mao, Taiwan; L. R. Maxson, USA; R. W. McDiarmid, USA; *G. Nilson, Sweden; *G. Pasteur, France; E. R. Pianka, USA; J. B. Rasmussen, Denmark; *A. de Ricqlès, France; *O. Rieppel, Switzerland; Z. Rocek, Czech Republic; *B. Sanchíz, Spain; *Y. Sawai, Japan; R. Shine, Australia; M. P. Simbotwe, Zambia; *Z. Spinar, Czech Republic; I. R. Swingland, UK; *L. P. Tatarinov, Russia; *F. Tiedemann, Austria; R. C. Tinsley, UK; L. Trueb, USA; *M. J. Tyler, Australia; R. Wassersug, Canada; *G. R. Zug, USA.

SEIBERT AWARDS FOR BEST STUDENT PAPERS

AT LAST YEAR'S MEETING IN EL PASO, TEXAS, THE SSAR established two prizes to be awarded for the best student papers presented at each annual meeting. These awards are named in honor of Henri C. Seibert, Professor of Zoology Emeritus at Ohio University, who served the SSAR as its President, Treasurer, and Publications Secretary at different times over a period of nearly 30 years. He also played a key role in the transformation of The Ohio Herpetological Society into the SSAR.

Over the years, Henri Seibert has helped hundreds of young herpetologists throughout the world by patiently answering their numerous queries, by putting them into contact with others having similar interests, and by generally encouraging their interest in herpetology. Many SSAR members fondly remember the helpful advice they received years ago from Henri Seibert and some can even trace their present career to his gentle encouragement.

ENDOWMENT TO BE ESTABLISHED

To maintain the Seibert Awards in perpetuity, SSAR has decided to establish an endowment of US$10,000 for this purpose. All donations to SSAR are income-tax deductible and may be addressed to:

Dr. Douglas H. Taylor, SSAR Treasurer,
Department of Zoology, Miami University,
Oxford, Ohio 45056, USA.

Make checks payable to "SSAR" and mark "For Seibert Fund." We encourage all SSAR members—especially Henri's many friends and correspondents around the world—to contribute to this worthy fund.

Venue.—Individuals or groups who wish to propose sites for the Third Congress (to be held 1996-1999) should submit one-page-maximum proposals indicating meeting and housing facilities, names of persons who might serve as local Organizing Committee, and special attractions of the site (until 15 November 1993).

Nominations and venue proposals should be submitted to the Secretary-General: *Dr. Marinus S. Hoogmoed, Nationaal*

Natuurhistorisch Museum, Postbus 9517, 2300 RA Leiden, The Netherlands.

Sale Of UMMZ Publications

The Museum of Zoology at the University of Michigan is having a sale on its in-print publications, including many authored by L. C. Stuart. *Miscellaneous Publications, Occasional Papers, Publications of the Laboratory of Vertebrate Biology, Circulars, Special Publication 1* ("How Humans Evolved: The Uniquely Unique Species" by R. D. Alexander), and all publications not part of any of the preceding series are included. Sale terms: 5-10 publications, 30% off, and over 10 publications, 50% off of price listed in current catalogue of publications. Shipping and handling charges additional. Sale ends 31 December 1993. Quantities limited; first come/first served. For current catalogue and order form please write:

Publications
Museum of Zoology
1109 Geddes Rd.
The University of Michigan
Ann Arbor, Michigan 48109-1079, USA.

National Center For The Conservation And Management Of Amazon Turtles

The National Center for the Conservation and Management of Amazon Turtles (CENAQUA) is a Brasilian government funded project in operation since 1979 as part of IBAMA (Brasilian Fish and Wildlife Service). The objectives of the project are to establish permanent stations for the protection of nesting areas, basic research, captive rearing, and environmental education jointly with the river communities. The focal species are the Amazon river turtle or tartaruga (*Podocnemis expansa*), tracajá (*P. unifilis*), and iaçá (*P. sextuberculata*). These species are most utilized for food by the riverine communities and suffer the greatest pressure during the nesting season, not just for their meat but also for their eggs.

Recently, the project has been elevated to the status of a center, which is more autonomous and more stable. With this, more positions were opened for technicians working with freshwater turtles and a separate floor with office, laboratory, and computer facilities was built for the center in Goiás. Journals, reprints, and other general information are needed for the library. This year they will be constructing and equipping field laboratories at four sites in different parts of the Amazon. Herpetologists with laboratory or field equipment which is outdated or no longer in use, or with duplicate journal sets, reprints, or books should consider making a donation to the library and laboratories. Library materials can be shipped to the Smithsonian, which has a service for mailing to Third World libraries (Smithsonian International Exchange Service, 1111 North Capitol St., N.E., Washington, D.C. 20560, USA). If you have substantial amounts of laboratory equipment, arrangements can be made for free air transport to Brasil on Varig Airlines. For information concerning air shipments, contact:

Vitor Hugo Canterelli
CENAQUA/IBAMA Rua 229 #95
Goiânia, Goiás, Brasil
FAX 62-225-0770.

Herp-Net Installs High-Speed Access Line

The Herpetology Online Network has installed high-speed access for 9600/14,400/38,000 bps V.32, V.42bis modems on 215-698-1905. Standard speeds of 300-2400 bps should continue to access Herp-Net via the bank of phone lines connected to 215-464-3562.

Herp-Net is a computer based information network serving herpetologists, veterinarians, hobbyists, conservationists, and others interested in reptiles or amphibians. Any communicating computer or terminal can access Herp-Net by direct dial 24 hours per day.

News, submissions, or information requests may also be faxed to 215-464-3561 or mailed on IBM disks or paper to: Mark Miller, System Administrator, Herpetology Online Network, P.O. Box 52261, Philadelphia, Pennsylvania 19115, USA.

Request For Reprints

Florida resident and SSAR member Larry David Wilson's reprint library was completely lost in 1992 as a result of Hurricane Andrew. The library had only recently been rebuilt in the aftermath of a fire. Larry's friends are soliciting assistance in rebuilding his reprint library. Authors who may still have reprints pertaining to Neotropical herpetology, or other herpetologists with duplicate material are urged to send these to:

Larry David Wilson
Department of Biology
Miami-Dade Community College - Kendall Campus
Miami, Florida 33176, USA.

Request For Assistance

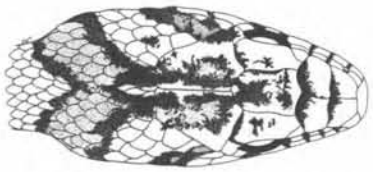
I am currently investigating the conservation genetics of threatened populations of black rat snakes (*Elaphe obsoleta*) and fox snakes (*E. vulpina*) in Ontario, Canada. For comparative purposes we require blood (from live specimens) or tissue (from roadkilled specimens) secured from populations located outside of Ontario. If you are interested in the conservation of these snakes and are willing to assist me by (1) sampling snakes in the field or, (2) directing me to known hibernacula, I would like to hear from you before the spring of 1993.

Please note that my blood sampling protocol is simple, non-destructive, and is currently approved by Federal, Provincial, and University Animal Care Committees. Only small amounts of blood (0.1 cc) or tissue (1-2 g) are required and live specimens can be released immediately after sampling. All sampling will be done under State permit(s) where required by law.

The results of this research will be of practical value to natural resource managers and conservation biologists involved in the protection and recovery of these and other snake species generally, but will be particularly applicable to those populations contributing to the study. For further information please contact:

Kent Prior
Department of Biology
Carleton University
1125 Colonel By Drive
Ottawa, Ontario
Canada K1S 5B6
Tel. (613) 788-2600 ext. 3866
FAX (613) 788-4497.

Information Request



The Wildlife Clinic of Tufts University School of Veterinary Medicine is compiling a database on the health parameters of native wildlife species. We currently have partial information on over 175 species, but we need your help. Although natural history information is readily available, we are having difficulty in finding information in the scientific literature on the hematology and clinical chemistry of many native mammals, birds, and herps.

If you have such information in your files, would you consider sharing it with the broader wildlife community? Even if you only have laboratory values for one individual of one species, this constitutes valuable information. We are also interested in finding out about any literature on the subject that you might be familiar with. We will compile all available information and make it widely available. For their participation, anyone contributing data will receive full attribution and a copy of the database.

Once our database is a bit more complete we will make it available to veterinarians, wildlife rehabilitators, and wildlife biologists by posting it on electronic networks such as Econet, and making available both hard copy and diskette versions at our cost.

Data can be contributed as hard copy, or 3.5-inch diskettes in any standard word processing format or as ASCII files. Please send data to:

Mark Pokras, DVM
Tufts Wildlife Clinic
200 Westboro Rd.
North Grafton, Massachusetts 01536-1895, USA
Tel. (508) 839-7918
FAX (508) 839-7930.

Thamnophis sumichrasti. USNM 7079(a). Illustration by J. W. Tamplin.

MEETINGS

16th Annual All Florida Herpetological Conference

The All Florida Herpetological Conference will be held Saturday, 17 April 1993 at the University of Florida in Gainesville. The event is cosponsored by the Florida Museum of Natural History and the Gainesville Herpetological Society. Talks will cover a wide range of subjects, from autecology to captive breeding of amphibians and reptiles. The evening barbecue will be held at the Florida Museum of Natural History. For program and registration information, write or call:

Dr. David L. Auth
Division of Herpetology
Florida Museum of Natural History
University of Florida
Gainesville, Florida 32611, USA
Tel. (904) 392-1721.

1993 Annual Meeting: The Society For Northwestern Vertebrate Biology

The Society for Northwestern Vertebrate Biology (SNVB) will hold its annual meeting Thursday, March 18 through Friday, March 20, 1993 at the Red Lion Inn in Astoria, Oregon. This meeting will have a heavy emphasis on the status of amphibians in the Northwest. Two symposia of invited papers will be held: Declining Amphibian Populations and Amphibian Monitoring in Western National Parks. Papers from the latter symposium will be submitted for publication either in an issue of *Northwestern Naturalist* or separately in the monograph series *Northwest Fauna*. This proceedings issue will be sent to all members of SNVB, but it will also be available for purchase. SNVB needs to have a rough idea of the number of copies needed, however. If you are interested in purchasing proceedings of the symposium, "Amphibian Monitoring in Western National Parks," or are interested in joining SNVB ($15 per year), drop a note to *Stephen Corn, U.S. Fish and Wildlife Service, 4512 McMurry Avenue, Ft. Collins, Colorado 80525-3400, USA; phone (303) 226-9464*. This expression of interest is not an order and will in no way constitute an obligation to purchase the proceedings.

Other amphibian-related activities planned at the SNVB meeting include a workshop on monitoring techniques, a live display of northwestern herpetofauna, and tentatively, a field trip to Long Island on the Willapa National Wildlife Refuge.

The meeting will also have open sessions for contributed papers and posters on any aspect of the biology of northwestern vertebrates. There will be a social (no-host bar) on Thursday evening.

For more information, or to submit an abstract for a contributed paper or poster, please contact *Larry Jones, Pacific Northwest Research Station, Forestry Sciences Laboratory, 3625 93rd Avenue, S.W., Olympia, Washington 98502, USA; phone (206) 956-2345*.

Third Latin American Congress Of Herpetology

The 3rd Latin American Congress of Herpetology (3rd CLAH) will be held at the Campinas State University, in Campinas, São Paulo, Brazil, 12-18 December 1993. The objective of the Congress is to promote and integrate the various aspects of research among scientists and students working in neotropical herpetology.

The official languages of the 3rd CLAH to be used in the mini-courses, conferences, and oral presentations will be Portuguese and Spanish. However, English and French will be accepted in poster presentations, workshops, symposia, and in some conferences and oral presentations.

Oral presentations will be arranged in topical sessions. Workshops will be pre-arranged and/or organized during the congress according to participants' interest. One-day trips and post-congress excursions are being planned. Participants are limited to two abstracts and their corresponding presentations with registration. Students' registration includes attendance in one mini-course. Abstracts should be submitted to the Organizing Committee in Brazil. The deadline for abstracts to be published is 30 June 1993. A second circular appeared in late February 1993, and was mailed only to registered participants or individuals who have requested to receive it.

For registration, mailing requests, abstract forms, or additional information please contact:

Dr. Rafael O. de Sá

Fourth Symposium On Resources Of The Chihuahuan Desert Region: United States And México

Call for Papers: The Fourth Symposium on Resources of the Chihuahuan Desert Regions: U.S. and México will be held on the campus of the University of Texas at El Paso 30 September - 2 October, 1993. The theme for the Fourth Symposium will be "Conservation and Sustainable Development of Chihuahuan Desert Resources." The objectives are to 1) promote international cooperation among scientists, institutions, agencies, and organizations; 2) build on previous data by seeking to determine how resources are being used, managed, threatened, and depleted; 3) provide new information on sustainable approaches to ecological concerns and the preservation of Chihuahuan resources; 4) expose participants to the scope of current research activities in the region; and 5) allow for a clear understanding of future research and management priorities. Each presentation will be 18 minutes in length with two minutes for questions. Presentations can be made in either English or Spanish. Authors will have the option of submitting their paper for publication in the Symposium Proceedings. Session topics include: Vertebrate Zoology; Invertebrate Zoology; Ecology; Wildlife Biology; Botanical Sciences; Aquatic and Riparian Habitats; Geology, Paleontology, and Hydrology; and Anthropology, Archaeology, and Ethnology.

Abstracts: Each abstract must be typed double-spaced on an 8.5 x 11 inch sheet of paper. List the author(s), affiliation(s), and current address(es). Abstracts should not exceed 200 words. Please submit a diskette with a hard copy if possible. All abstracts must be postmarked no later than 15 June 1993. Send abstracts to: *Chihuahuan Desert Symposium, CRDI, P.O. Box 1334, Alpine, Texas 79831, USA, or call (915) 837-8370 for additional information.*

Second World Congress of Herpetology

29 December 1993 – 6 January 1994

LEGISLATION & CONSERVATION ALERT

Call for information on the status of amphibians and reptiles: This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles. We are in need of more information, especially at the State or Province level. Please send pertinent information to the Section Editor.

The following final and/or proposed listings, regulations, and general information have been announced by governmental regulatory agencies. Pertinent *Federal Register* (FR) citations are given for U.S. notices.

USA: Louisiana: The Louisiana legislature has passed a set of revised statutes that will regulate taking and sale of reptiles and amphibians in the state. These statutes take effect 1 July 1993. The content of the new regulations is largely a product of a 16-person task force including SSAR members Harold A. Dundee, Douglas A. Rossman, and Richard A. Seigel, plus representatives from the Louisiana Department of Wildlife and Fisheries, Louisiana Department of Agriculture and Forestry, commercial pet dealers, Louisiana Cooperative Extension Service, and the Louisiana Science Teachers Association. The regulations will be enforced by the Department of Wildlife and Fisheries and the Task Force will continue to act in an advisory capacity. Violations are punishable by fines. Alligators are covered by an independent set of regulations. A condensed summary follows:

- Wholesale/retail dealers and personal collectors must have a license. (Fee involved). Researchers must obtain a collecting permit (no fee).
- Authority to prohibit harvest rests with Louisiana Department of Wildlife and Fisheries.
- There are specific regulations for method of collection. Use of gasoline is prohibited, cover objects must be returned to original positions, traps must be labeled.
- Specific regulations are listed for *Rana catesbeiana*, *R. grylio*, and *Malaclemys terrapin*.
- A Reptile and Amphibian Research Fund is to be funded from fees collected.

All interested herpetologists should obtain a complete copy of the new Loulsiana regulations from the Department of Wildlife and Fisheries, P.O. Box 98000, Baton Rouge, Louisiana 70898-9000, USA.

USA: *Ambystoma californiense* (California tiger salamander). The U.S. Fish and Wildlife Service currently is evaluating the status of the California tiger salamander and has been petitioned to list it as an endangered species pursuant to the Endangered Species Act of 1973, as amended. Population declines have been attributed to loss of habitat to agriculture, urban development, and fish introductions.

Any herpetologists who have biological information useful to the USFWS's evaluation of this species should contact Mike Long, USFWS, 2800 Cottage Way, Room E-1823, Sacramento, California 95825-1846, Tel. (916) 978-4866. FR 57(224):54545-54546.

KURT A. BUHLMANN
SSAR Conservation Committee.

REGIONAL SOCIETIES

Directory Of U.S. Regional Herpetological Societies

The list below contains names and addresses of all regional herpetological societies in the U.S. as of October 1992. Additions or corrections to this list should be brought to the attention of the Regional Society Section Editor (name and address on inside front cover).

American Federation of Herpetoculturists
P.O. Box 1131
Lakeside, California 92040-0905, USA

Arizona Herpetological Association, Inc.
P.O. Box 39127
Phoenix, Arizona 85069-9127, USA

Arkansas Herpetological Society
c/o Glyn Turnipseed
418 North Fairbanks
Russellville, Arkansas 72801, USA

Bay Area Amphibian & Reptile Society
Palo Alto Junior Museum
1451 Middlefield Road
Palo Alto, California 94301, USA

Blue Ridge Herpetological Society
P.O. Box 727
Brookneal, Virginia 24528, USA

California Turtle & Tortoise Club
P.O. Box 7300
Van Nuys, California 91409-7300, USA

Central Florida Herpetological Society
P.O. Box 3277
Winter Haven, Florida 33881, USA

Central Illinois Herpetological Society
1125 West Oak
Peoria, Illinois 61614, USA

Central Kentucky Herpetological Society
P.O. Box 12227
Lexington, Kentucky 40581-2227, USA

Central Ohio Herpetological Society
217 East New England Avenue
Worthington, Ohio 43085, USA

Chicago Herpetological Society
2001 North Clark Street
Chicago, Illinois 60614, USA

Chihuahuan Desert Herpetological Society
Box 3AF
New Mexico State University
Las Cruces, New Mexico 88001, USA

Colorado Herpetological Society
P.O. Box 15381
Lakewood, Colorado 80215, USA

Horned Lizard Conservation Society

The Horned Lizard Conservation Society (HLCS) is a non-profit corporation founded in November of 1990. The purpose of the society is to document and publicize the values and conservation needs of horned lizards (genus *Phrynosoma*), to promote horned lizard conservation projects, and to assist with horned lizard management initiatives throughout their ranges.

Horned lizard populations have apparently decreased throughout much of their historical range within the last fifty years. The factors responsible for these declines are probably many and complex. However, the declines themselves, as well as their causes, remain undocumented and subject to speculation. HLCS seeks to address this situation by gathering and organizing existing information, developing and supporting research on horned lizard ecological requirements and population demographics, developing strategies for the management of horned lizard habitat, and educating the public about the conservation needs of the genus.

Membership dues are: students $10, subscribing $10, regular $25, and contributing $50. Dues support research, conservation, and education efforts, and members receive the society's quarterly newsletter, *Phrynosomatics*. Formal group meetings are held quarterly in Austin, Texas. Those interested in joining HLCS or in receiving information should contact:

Horned Lizard Conservation Society
P.O. Box 122
Austin, Texas 78767, USA.

POINTS OF VIEW

Viewpoint: A Reply To Collins (1991, 1992)

It seems that in every decade there is an attempt to "simplify" some complex biological problem by a wholesale change in procedures, the introduction of a new concept, or a brand-new paradigm. In some of these cases, where there is a rational basis for a change, a residue of beneficial ideas or techniques remains after the "new" item has been tried, tested, and then found to be unworkable as proposed. In others, wherein no new techniques are offered—merely a change in practice, or a different viewpoint (as in the present case)—little has been gained after the dust has settled. This history suggests that when dealing with complex biological problems, reductionism is not the proper approach.

The current suggestion of the wholesale raising of many North American amphibian and reptile subspecies to full species rank (on the basis of the "Evolutionary Species Concept") without providing data that would substantiate such change (Collins 1991), is reminiscent of the suggestion by Smith and Taylor (1950) that questionable type localities of Mexican reptiles and amphibians be arbitrarily determined. The ensuing replies (Dunn and Stuart 1951a, 1951b) left little question that this was a poor idea; such decisions should be based upon careful, monographic studies.

On the other hand, the promulgation of numerical taxonomy in the 1960's (Sokal and Sneath 1963), though later having been shown to be based upon false premises (at least in regard to the evolutionary significance of morphological differences), has promoted the development of numerous mathematical procedures and led to later developments of current computer techniques. Similarly, although not everyone (in fact, perhaps no one) follows the precepts of Hennig (1966) in every respect, his ideas began to have a beneficial effect on taxonomic procedure, particularly after the many discussions of cladistics versus evolutionary systematics in the journal *Systematic Zoology* in the 1970's.

I have no intrinsic opposition to the raising (or lowering) of species-level ranks, but I do believe that such actions require more study than looking at a published range map and checking a list of "definitive" features. In my experience the features used for subspecies recognition tend to differ from those used for species. Also, it should be remembered that whereas subspecies are defined upon geographic information and "differences" (remember the old 75% [or 85%] rule?), species are defined upon resemblances and *distinctions*—all of these presumed to be indicators of degrees of evolutionary relationships.

Also, having personally filled-in a number of apparent range gaps, I know that a gap on a map is not necessarily a gap in the range of an animal. Many animals are secretive or appear only under certain conditions of time and weather, and thus remain undiscovered for long periods. To cite one example indicated by Collins (1991:43), I am confident that the persisting "map-gap" in the range of *Scaphiopus holbrooki/hurteri* is not as shown (Conant and Collins 1991: map 273). In the mid-1950's I was attending the meeting of the Arkansas Academy of Science at Harding College, in the Arkansas River Valley near the edge of this "gap." A thunderstorm came up during the annual banquet, and when I walked out onto the campus after the dinner I could hear a large chorus of *Scaphiopus* calling from a small pond. Even then we knew that the contact zone between *holbrooki* and *hurteri* was a critical issue, so I laid my jacket and shoes on the grass, rolled up

my sleeves and pants-legs, and waded out. Unfortunately, I had no headlight and the spadefoots could see me in the moonlight, and ducked under as soon as I got near. So, I was unable to catch a single one. That's the only reason that part of the gap is still there. I can see no ecological reason that would prevent *Scaphiopus* from inhabiting the entire length of the valley—all the way to the Mississippi River—it is just that no knowledgeable herpetologist has been there at the critical time.

In a more philosophical vein, I will agree that the subspecies taxon has been badly used (misused, over-used) in many studies. In reference to snakes, with which I am most familiar, I also find some of the "subspecies" unconvincing in *Arizona, Cemophora, Diadophis, Elaphe,* and *Pituophis*. Perhaps some of the forms mentioned by Collins should be raised to species rank. It seems equally possible that some of them, or their (current) conspecific relatives, should not be recognized at any taxonomic level. But I would **NOT** presume to make these changes without presenting **ADEQUATE DATA**.

It is true, also, that the species category has been badly misused in some studies. It is clear that small, secretive snakes do not have large home ranges and tend to form small populations that differ from one another in varying degrees. This is particularly true in regions that have been subject to considerable environmental change during the Pleistocene or thereafter. It does not take much work to show that such populations "differ" from one another—particularly if the samples are small. However, it seems to me very difficult to show that they are on "different phylogenetic trajectories" (Frost and Hillis 1990:92), and I do not believe that an **apparent gap in** a distribution map plus a list of **presumed** morphological differences is an adequate procedure to confirm this—even if that definition of a species is accepted. Thus, I believe that both sides of the coin need to be extensively investigated: not only the validity of recognized subspecies, but also the validity of recognized species. Obvious starting points for the latter include close examination of the current taxonomy of *Geophis* and *Tantilla*.

My main objection to Collins's (1991) paper, however, is that no data are presented to support these changes in nomenclature. Rather than agreeing to "encourage the adoption of the taxonomic arrangement listed above" (Collins 1991), I would encourage workers to **investigate** the putative relationships of these taxa. If we follow Collins's recommendation, we merely substitute one unknown for another—to the detriment of the available information. At present we have some assurance that *Lampropeltis calligaster occipitolineata* bears some relationship to *L. calligaster*, but we would have no such assurance with his "*L. occipitolineata*," which might be more closely related to *L. getulus*, or to *L. triangulum*, or to some other species in so far as the nomenclature indicates. Even worse are the subspecies of some American snakes that are in Holarctic genera such as *Coluber* and *Elaphe*—or how about the cosmopolitan genus *Eumeces*? Isn't it better to know that these taxa have American relationships?

It is my belief that the subspecific category has many advantages when properly utilized (as a related, but different, geographic population). At worst it alleges that a population resembles one species more than it does another in certain (usually morphological) characters. At best it is a distinctive (NOT distinct) series of populations with recognizable suites of features that occupy defined ranges, and which often have different habits and ecologies. They may continue, perhaps in reduced fashion, to interbreed with their adjacent populations through broad or narrow areas of intergradation. But this latter should not be required blindly. Evolutionarily speaking, the Pleistocene was only yesterday. It is as easy to guess that the temporary barriers between incompletely differentiated populations extant today will be breached tomorrow as it is to **guess** at the past time that the separation took place "**forever.**" Certainly, both are easier than guessing at their "phylogenetic trajectories."

There are many more tools available now to test the relationships of animals than there were even a decade ago. We only need to consider the advances in electrophoretic techniques, in immunological comparisons, in karyology, and in the various methods utilizing DNA transformations to see this. I would hope that some of these and other methods would be brought to bear on the questions of species *versus* subspecies (and what about genera?), rather than blindly substituting one taxonomic category for another because some worker feels that the concept is "outdated."

After writing the above comments, I received *Herpetological Review* 23(1) and thought that Montanucci (1992) and Van Devender et al. (1992) had rather well demonstrated that Collins's action was in error. Later, upon reading his attack on these workers and their ideas in *Herpetological Review* 23(2), however, it became clear that Collins (1992) had missed the basic reasoning of their objections. Thus, I feel compelled to enter this unfortunate conflict.

First, it is not a question of people trying to push Collins off his "philosophical mountain" of the "Evolutionary Species Concept" (ESC)—in science anyone is welcome to believe any concept that they choose. It is his "recommendation" that everyone follow in his footsteps in the raising of these subspecies to species level WITHOUT PRESENTING ANY DATA to support this idea that is the problem. His admission that "Thus, my recent list (Collins 1991), which was prepared **without testing the validity** of the species in question . . ." is the crux of the matter. This is not the way that science works! New ideas must be **substantiated** to be acceptable to their audience. Now for some specifics:

1) Collins stated: "55 subspecies . . . were already diagnosed . . . in their original descriptions . . . if they had not been so diagnosed, they would not be recognized at all." Such a statement is patently untrue. Most taxa are currently recognized, not on the basis of their original descriptions (try Linnaeus 1758, or Cope 1861, for original descriptions!), but are based upon subsequent, careful revisionary (often monographic) studies. He is badly mistaken in his belief that perusal of original descriptions is an adequate method of determining the status of a taxon. And, it is **not logic** that is required in raising a taxon from subspecies to species rank, it is **adequate data.**

2) It would seem unnecessary to point out, as Collins (junior author of a field guide) should know better than most, that the small, generalized maps in field guides are **not** the "best available published maps" (Collins 1992:43; cf. Collins 1991:43). Indeed, such maps are **always** wrong in detail (Axtell 1965). The best distribution maps, ordinarily, are found in monographs (e.g., Duellman 1958) or in some subsequent zoogeographical or state-based work (e.g., Mount 1975), and there is no question that those in the *Catalogue of American Amphibians and Reptiles* are far superior to those in the field guides.

3) I find it more than passing strange that the taxonomic status of an animal is now determined by "majority vote" of "groups of herpetological specialists" (Collins 1990:1; 1992:43). It is more usual scientific practice for taxonomic changes to be made on the basis of the information provided in the publication that proposes them. Certainly, a group of "specialists" (or any other group sitting at a bar), or any author alone can determine how he/she will treat a taxon in their own publications (e.g., Lazell 1972). This, however, gives no additional validity to that usage; again it is the substantiation of this change by the provision of data, and the acceptance of this as adequate by other herpetologists, that count.

4) In spite of Collins's repeated protestations (1992: 43, 44, 45) that his use of the ESC to raise subspecies to species rank is "conservative," this simply is not true. If a person who proposes a taxonomic change does not have detailed knowledge of the taxa affected, this is *ipso facto*, **not a conservative action.** The conservative approach would be to **defer** any action.

5) Back to subspecies definitions (Collins 1992: 44-45). It seems clear that there is no room for subspecies in Collins's view of ESC—and perhaps not in any view of this recent proposal of taxonomic recognition. According to Collins, "If the characters that supposedly distinguish . . . [any subspecies] are not diagnostic, then its evidential support is flawed and it does not deserve *even* [emphasis mine] subspecific status." Obviously, on this basis if the animals are not 100% distinct, they do not deserve any name. And, if they are 100% different, they must be species. Again, there is some confusion between the use of "different" and "distinct." Subspecies have never been required to be distinct—only recognizably different. Perhaps Collins has noted from the comments of his critics that the concepts of the biological species and of subspecies are "outdated" only in the minds of some.

In summary, Collins's methodology is reminiscent of, and perhaps an attempt to return to, "Taylor Taxonomy." E. H. Taylor was a very active and long-lived herpetologist (in Collins's same institution at Kansas) whom I admired in many respects. His working method, however, led to a plethora of species descriptions—many of which were later shown to be invalid. I was able to observe this methodology a number of times. Taylor would set out a number of museum specimens for study, and would methodically observe, measure, and record the various morphological features of each specimen. If he came upon one that appeared different or otherwise interesting, he would consult the *original descriptions* of appropriate, presumably similar taxa, and compare those *descriptions* with the specimen in hand. If the specimen differed (or was distinguishable) from the characteristics described by the previous authors, it was obviously a different taxon, and so he described it as new. Collins's method is similar, but **without** the close examination of specimens.

A final word on Collins's (1992) view of science. In his final paragraph before his Summary, he states that it has been suggested that ". . . the herpetological community review my list . . . but if they do, it *must be by the same criteria that I used* . . ." (emphasis mine). This is an unusual request. Ordinarily critics are not constrained by limits put upon their comments—nor is it appropriate here, inasmuch as, to a large extent, it is his criteria that are in question. I propose that Collins's suggestion on the "adoption of the taxonomic arrangement" be rejected. As was noted in a somewhat similar case, I find his suggestion to be "without legal status ('incompetent, irrelevant, immaterial'": Dunn and Stuart 1951b), and do not consider it a constructive effort in herpetological taxonomy.

A Consensus On The Spelling Of Certain Snake Family-Group Names

The publication of McDowell (1987) and other papers in that volume sparked a minor controversy over the spelling of names of snake family-group taxa formed from the Greek stem *ophis* which were emended without comment such that Thamnophiini became Thamnopheini, etc. Smith and Preston (1987) justified these emendations by claiming that *ophe-* and not *ophi-* was the correct stem for such names. The stated objective of the International Code of Zoological Nomenclature is to "... promote stability and universality in the scientific names of animals and to ensure that the name of each taxon is unique and distinct" (International Commission on Zoological Nomenclature 1985:3). To this end the Code contains many rules governing the formation and spelling of the names of taxa, and errors in formation must be corrected.

In a response to Smith and Preston (1987), Cannatella (1990) argued that according to the Code both *ophe-* and *ophi-* were acceptable because the forms *opheos* and *ophios*, from which the stem

is formed, were dialectical variants of the genitive singular, and either variant was accepted as valid Ancient Greek. Given that Article 32b states that the original spelling is to be maintained unless it is shown to be clearly incorrect, Cannatella concluded that names such as Thamnopheini were unjustified emendations, and therefore invalid, but available as junior objective synonyms.

In opposition to Cannatella (1990), Smith and Chiszar (1992) and Smith and Smith (1992), argued that Appendix D VII, Table 2 of the Code provided a counterexample in the word *krisis*. For purposes of family-group names the stem is given as *krise-*, not *krisi-*. Because Article 29b (dealing with determination of the stem) explicitly defers to Appendix D, these authors stated that *ophe-* was correct and *ophi-* was incorrect. They further argued that maintenance of the long-established spellings could be assured by appeal to the Commission, but that such intervention was not necessary because no confusion in application of names would result from the emendations.

The first author of this note (DCC) argued (in litt.) that Appendices A through E have the force of recommendations, not rules (International Commission on Zoological Nomenclature 1985:1) and therefore both stems are correctly formed. In a letter in response to a query by the second author (HMS), Philip Tubbs, Secretary of the International Commission on Zoological Nomenclature, offered the same opinion, vouchsafing for the Commission that the original spellings (in all cases with *ophi-* as the stem for family-group names) must be maintained; only by exercise of its plenary powers could the Commission require use of *ophe-* as the stem, and this it likely would not do. Therefore, we now agree that the spellings in common usage, with *ophi-* as the stem, should be maintained. Emendations such as Thamnopheini and Hydropheidae are unjustified emendations, but available as junior objective synonyms in the sense of the Code.

Issues such as this one explain the disdain with which many biologists sometimes view the efforts of taxonomists. Some of these efforts are necessitated by overly legalistic aspects of the Code, but perhaps many such issues need not be dealt with at all, at least in print. Given that recent efforts of the Commission (Savage 1990) indicate a move away from such exercises, systematists can turn their attention to more substantive issues.
